J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as `AArch32.FunctionName`. Some of these functions have an equivalent AArch64 function, `AArch64.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch32/debug/breakpoint`.

———— Note ————

Many AArch32 pseudocode functions have not been updated to show the constraints on the ARMv7 UNPREDICTABLE behaviors that are described in [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#). Where AArch32 pseudocode shows something to be UNPREDICTABLE, check [Appendix K1](#) for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- [aarch32/debug](#).
- [aarch32/exceptions](#) on page J1-7016.
- [aarch32/functions](#) on page J1-7035.
- [aarch32/translation](#) on page J1-7064.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- [aarch32/debug/VCRMatch/AArch32.VCRMatch](#).
- [aarch32/debug/authentication/AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled](#) on page J1-7009.
- [aarch32/debug/breakpoint/AArch32.BreakpointMatch](#) on page J1-7009.
- [aarch32/debug/breakpoint/AArch32.BreakpointValueMatch](#) on page J1-7010.
- [aarch32/debug/breakpoint/AArch32.StateMatch](#) on page J1-7011.
- [aarch32/debug/enables/AArch32.GenerateDebugExceptions](#) on page J1-7012.
- [aarch32/debug/enables/AArch32.GenerateDebugExceptionsFrom](#) on page J1-7012.
- [aarch32/debug/pmu/AArch32.CheckForPMUOverflow](#) on page J1-7013.
- [aarch32/debug/pmu/AArch32.CountEvents](#) on page J1-7013.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState](#) on page J1-7014.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState](#) on page J1-7014.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterMonitorModeInDebugState](#) on page J1-7015.
- [aarch32/debug/watchpoint/AArch32.WatchpointByteMatch](#) on page J1-7015.
- [aarch32/debug/watchpoint/AArch32.WatchpointMatch](#) on page J1-7016.

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

The top-level sections of the shared pseudocode hierarchy are:

- [shared/debug](#).
- [shared/exceptions](#) on page J1-7105.
- [shared/functions](#) on page J1-7107.
- [shared/translation](#) on page J1-7184.

J1.3.1 shared/debug

This section includes the following pseudocode functions:

- [shared/debug/ClearStickyErrors/ClearStickyErrors](#) on page J1-7087.
- [shared/debug/DebugTarget/DebugTarget](#) on page J1-7087.
- [shared/debug/DebugTarget/DebugTargetFrom](#) on page J1-7088.

Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- [AArch32 CONSTRAINED UNPREDICTABLE behaviors on page K1-7194.](#)
- [AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-7218.](#)

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- *Overview of the constraints on ARMv7 UNPREDICTABLE behaviors on page K1-7195.*
- *Using R13 on page K1-7195.*
- *Using R15 on page K1-7195.*
- *Branching into an IT block on page K1-7196.*
- *Branching to an unaligned PC on page K1-7196.*
- *Loads and Stores to unaligned locations on page K1-7196.*
- *CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-7196.*
- *Unallocated System register access instructions on page K1-7197.*
- *SBZ or SBO fields T32 and A32 in instructions on page K1-7198.*
- *UNPREDICTABLE cases in immediate constants in T32 data-processing instructions on page K1-7198.*
- *UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions on page K1-7199.*
- *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7199.*
- *CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-7200.*
- *Translation Table Base Address alignment on page K1-7200.*
- *Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-7200.*
- *The Performance Monitors Extension on page K1-7201.*
- *The Activity Monitors Extension on page K1-7202.*
- *Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-7203.*
- *Out of range VA on page K1-7203.*
- *Instruction fetches from Device memory on page K1-7204.*
- *Multi-access instructions that load the PC from Device memory on page K1-7204.*
- *Programming CSSELR.Level for a cache level that is not implemented on page K1-7204.*
- *Crossing a page boundary with different memory types or Shareability attributes on page K1-7204.*
- *Crossing a 4KB boundary with a Device access on page K1-7205.*
- *UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7205.*
- *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings on page K1-7206.*
- *Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7206.*
- *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-7207.*
- *CONSTRAINED UNPREDICTABLE behavior; A32 and T32 Advanced SIMD and floating-point instructions on page K1-7209.*

- [CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-7217.](#)

K1.1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

———— **Note** —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of **PSTATE**.{N, Z, C, V}, **PSTATE**.Q, and **PSTATE**.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,

In addition, for MRC instructions that use R15 as the destination register descriptor, and therefore target **APSR_nzcv** where these are described as being CONSTRAINED UNPREDICTABLE, **PSTATE**.{N, Z, C, V} becomes UNKNOWN.

K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its [Condition code check](#) within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the [Condition code check](#).

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
 - The unaligned address generates an exception on the first instruction using the unaligned PC value. If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
 - EL2 is using AArch32 and the value of [HCR.TGE](#) is 1.
 - EL2 is using AArch64 and the value of [HCR_EL2.TGE](#) is 1.If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1. If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.
- In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2785](#).
- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see [Prefetch Abort exception reporting a PC alignment fault exception on page G1-5282](#).

———— **Note** —————

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of [IFAR](#), [HIFAR](#), or [FAR_ELx](#) is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the [Condition code check](#).
- The instructions execute as NOPs. This means that they behave as if they had failed the [Condition code check](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

- PSTATE.IT is cleared to 0.
- PSTATE.IT advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

———— **Note** ————

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they had failed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in [Branching into an IT block on page K1-7196](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to '00000000'. The reserved values are:

```
PSTATE.IT[7:4] != '0000' && PSTATE.IT[3:0] = '0000'
PSTATE.IT[2:0] != '000' when SCTLR/SCTLR_EL1.ITD == '1'
```

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the PSTATE.IT bits set to a value other than '00000000'.
- Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they failed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in [Branching into an IT block on page K1-7196](#).

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

- The PSTATE.IT state machine advances as if it were in an IT block.
- The PSTATE.IT bits are ignored.
- The PSTATE.IT bits are forced to '00000000'.

K1.1.8 Unallocated System register access instructions

In ARMv8-A, accesses to unallocated System register encodings are UNDEFINED.

This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- MCR or MRC accesses to using a set of {coproc, CRn, opc1, CRm, opc2} values that the ARMv7 architecture defined as UNPREDICTABLE.
- Accesses to System registers in the (coproc==0b111x) encoding space that the ARMv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an ARMv8 implementation does not include the Exception level that provides that functionality.

K1.1.9 SBZ or SBO fields T32 and A32 in instructions

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- [LDM, LDMIA, LDMFD](#) on page F5-3962.
- [LDMDB, LDMEA](#) on page F5-3972.
- [LDR \(literal\)](#) on page F5-3981.
- [LDRB \(literal\)](#) on page F5-3991.
- [LDRD \(immediate\)](#) on page F5-3999.
- [LDRD \(register\)](#) on page F5-4005.
- [LDRD \(literal\)](#) on page F5-4002.
- [LDRH \(literal\)](#) on page F5-4020.
- [LDRSB \(literal\)](#) on page F5-4031.
- [LDRSH \(literal\)](#) on page F5-4042.
- [POP](#) on page F5-4149.
- [PUSH](#) on page F5-4156.
- [SDIV](#) on page F5-4235.
- [STM, STMIA, STMEA](#) on page F5-4328.
- [STMDB, STMFD](#) on page F5-4336.
- [UDIV](#) on page F5-4450.

K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing [Modified immediate constants in T32 instructions](#) on page F2-3669 include constant values that were UNPREDICTABLE in ARMv7. [Instruction encodings](#) on page F2-3650 describes 32-bit T32 instructions as {hw1, hw2}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

- hw2[7:0] == 0b0000000.
- hw1[10] == 0 and either:
 - hw2[14:12] == 0b001.
 - hw2[14:12] == 0b010.
 - hw2[14:12] == 0b011.

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value 0b0000000.

K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-3671 include constant values that were UNPREDICTABLE in ARMv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as *abcd* are all 0.
In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits {hw1[12, 2:0], hw2[3:0]}.
- The bits that the encoding diagram shows as *cmode*[3:1] are one of {0b001, 0b010, 0b011, 0b101, 0b110}.
In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits hw2[11:9].

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes [ARMv8.2-TTCNP](#), this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting [TTBR.CnP](#) to 1, as identified in the descriptions of the [TTBR.CnP](#) field. In this case, for a particular [TTBR](#), the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that [TTBR](#) on one of the PEs within the Inner Shareable domain for which both the value of [TTBR.CnP](#) is 1 and the other conditions for sharing translation table entries pointed to by that [TTBR](#) are met.
- An amalgamation of the values of the translation table entries pointed to by that [TTBR](#) on two or more of the PEs within the Inner Shareable domain for which both the value of [TTBR.CnP](#) is 1 and the other conditions for sharing translation table entries pointed to by that [TTBR](#) are met.

———— Note —————

If the *Effective value* of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that *Effective value* must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a [TTBR.CnP](#) value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that [TTBR](#) and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see [TLB conflict aborts](#) on page G5-5527.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.1.14 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and `TTBR0[13-N:7]`, which is defined to be `RES0`, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and `TTBR0[x-1:3]`, `TTBR1[x-1:3]`, `HTTBR[x-1:3]`, or `VTTBR[x-1:3]`, which are defined to be `RES0`, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be `RES0` is treated as if all bits were zero:
 - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

K1.1.15 Handling of System register control fields for Advanced SIMD and floating-point operation

For historical reasons described in *Background to the System register interface on page G1-5306*, each of the `CPACR`, `HCPTR`, and `NSACR` has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- `CPACR`.{cp10, cp11}.
- `HCPTR`.{TCP10, TCP11}.
- `NSACR`.{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11, or TCP11, control field was equal to the cp10, or TCP10, field in all respects other than the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

———— **Note** —————

This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

CONSTRAINED UNPREDICTABLE CPACR and NSACR settings

If `CPACR`.cp<n> contains the encoding '10', then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.

- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

———— **Note** —————

In ARMv7, [CPACR](#) had a D32DIS bit, and [NSACR](#) had an NSD32DIS bit. There is no [CPACR.D32DIS](#) or [NSACR.NSD32DIS](#) in ARMv8-A, and the corresponding bits in the two registers are RES0.

K1.1.16 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

- [CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR](#).
- [CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n> on page K1-7202](#).
- [CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN on page K1-7202](#).

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If [PMSELR.SEL](#) is not equal to 31, and [PMSELR.SEL](#) is greater than or equal to [PMCR.N](#), and the PE is executing in Secure state or in Non-secure Hyp mode.
- If [PMSELR.SEL](#) is not 31, and [PMSELR.SEL](#) is greater than or equal to [HDCR.HPMN](#), and the PE is executing in a Non-secure mode other than Hyp mode.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

- Accesses to [PMXEVTYPER](#) or [PMXEVCNTR](#) from that mode are UNDEFINED.
- Accesses to [PMXEVTYPER](#) or [PMXEVCNTR](#) from that mode behave as RAZ/WI.
- Accesses to [PMXEVTYPER](#) or [PMXEVCNTR](#) from that mode execute as NOPs.
- Accesses to [PMXEVTYPER](#) or [PMXEVCNTR](#) from that mode behave as if [PMSELR.SEL](#) contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to [PMXEVTYPER](#) or [PMXEVCNTR](#) behave as if [PMSELR.SEL](#) is 31.
- In Non-secure state, for an access to [PMXEVTYPER](#) or [PMXEVCNTR](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
 - EL1 is using AArch64 and the value of [PMUSERENR_EL0.EN](#) is 1.

If [PMSELR.SEL](#) is equal to 31, then one of the following behaviors must occur:

- Accesses to [PMXEVCNTR](#) are UNDEFINED.
- Accesses to [PMXEVCNTR](#) behave as RAZ/WI.
- Accesses to [PMXEVCNTR](#) execute as NOPs.
- Accesses to [PMXEVCNTR](#) behave as if [PMSELR.SEL](#) contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- In Non-secure state, for an access to [PMXEVCNTR](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.

- EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

———— **Note** —————

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, `HDCR.HPMN`, or `MDCR_EL2.HPMN`, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRAINED UNPREDICTABLE accesses to `PMEVCNTR<n>` and `PMEVTYPER<n>`

If `<n>` is greater than the number of counters available in the current Exception level and state, reads and writes of `PMEVCNTR<n>` and `PMEVTYPER<n>` are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- In Non-secure state, for an access to `PMEVCNTR<n>` or `PMEVTYPER<n>` from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of `PMUSERENR.EN` is 1.
 - EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

———— **Note** —————

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, `HDCR.HPMN`, or `MDCR_EL2.HPMN`, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRAINED UNPREDICTABLE behavior caused by `HDCR.HPMN`

If `HDCR.HPMN` is set to 0 or to a value greater than `PMCR.N`, then the CONSTRAINED UNPREDICTABLE behavior is:

- The value returned by a direct read of `HDCR.HPMN` is UNKNOWN.
- Either:
 - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if `HDCR.HPMN` is set to an UNKNOWN non-zero value less than `PMCR.N`.
 - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.1.17 The Activity Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Activity Monitors registers in AArch32 state:

- *CONSTRAINED UNPREDICTABLE accesses to `AMEVCNTR0<n>` and `AMEVTYPER0<n>`.*
- *CONSTRAINED UNPREDICTABLE accesses to `AMEVCNTR1<n>` and `AMEVTYPER1<n>` on page K1-7203.*
- *CONSTRAINED UNPREDICTABLE accesses to `AMCNTENCLR1` and `AMCNTENSET1` on page K1-7203.*

CONSTRAINED UNPREDICTABLE accesses to `AMEVCNTR0<n>` and `AMEVTYPER0<n>`

If `<n>` is greater than the number of architected activity monitor event counters, reads and writes of `AMEVCNTR0<n>` and `AMEVTYPER0<n>` are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.

- Accesses to the register execute as a NOP.

———— **Note** —————

[AMCGCR.CG0NC](#) identifies the number of architected activity monitor event counters.

CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n>

If <n> is greater than the number of auxiliary activity monitor event counters, reads and writes of [AMEVCNTR1<n>](#) and [AMEVTYPER1<n>](#) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

———— **Note** —————

[AMCGCR.CG1NC](#) identifies the number of auxiliary activity monitor event counters.

CONSTRAINED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of [AMCNTENCLR1](#) and [AMCNTENSET1](#) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

———— **Note** —————

The number of auxiliary activity monitor event counters implemented is zero exactly when [AMCFGR.NCG](#) == 0b0000.

K1.1.18 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:

- If this exception is taken to an Exception level that is using AArch64 then [ESR_ELx](#) is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the [HSR](#) is unknown.

———— **Note** —————

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.1.19 Out of range VA

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

K1.1.20 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.1.21 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the ARMv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

K1.1.22 Programming CSSELR.Level for a cache level that is not implemented

If [CSSELR.Level](#) is programmed to a cache level that is not implemented, then a read of [CSSELR](#) returns an UNKNOWN value in [CSSELR.Level](#).

If [CSSELR.Level](#) is programmed to a cache level that is not implemented, then on a read of [CCSIDR](#) an implementation must perform one of the following behaviors:

- The [CCSIDR](#) read is treated as a NOP.
- The [CCSIDR](#) read is UNDEFINED.
- The [CCSIDR](#) read returns an UNKNOWN value.

When [ARMv8.3-CCIDX](#) is implemented, [CCSIDR2](#) is implemented. If [CSSELR.Level](#) is programmed to a cache level that is not implemented, then on a read of [CCSIDR2](#) an implementation must perform one of the following behaviors:

- The [CCSIDR2](#) read is treated as a NOP.
- The [CCSIDR2](#) read is UNDEFINED.
- The [CCSIDR2](#) read returns an UNKNOWN value.

K1.1.23 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the mismatch then the resulting exception is taken to PL1.
- If the stage 2 translation causes the mismatch then the resulting exception is taken to PL2.

- If both stages of translation cause the mismatch then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

K1.1.24 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.
- If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.
- If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

———— **Note** —————

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

K1.1.25 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

[Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-3605](#) defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in ARMv7. In summary, these cases are:

- The target virtual address of a StoreExc1 instruction is different from the virtual address of the preceding LoadExc1 instruction in the same thread of execution.
- The transaction size of a StoreExc1 instruction is different from the transaction size of the preceding LoadExc1 instruction in the same thread of execution.
- The memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, either:
 - Because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction.
 - Because the LoadExc1 instruction and the StoreExc1 instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in [Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-3605](#) for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

Note

Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see [CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-7207](#).

K1.1.26 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings

In the A32 and T32 instruction sets, there are encodings of the [CRC32](#) and [CRC32C](#) instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

- [Cyclic Redundancy Check on page F4-3758](#) for the A32 instruction set, with $sz = 11$.
- [Data-processing \(two source registers\) on page F3-3744](#) for the T32 instruction set, with $op1 = 10x$ and $op2 = 11$.

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in [CRC32 on page F5-3907](#) and [CRC32C on page F5-3910](#).

CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

- [Miscellaneous on page F4-3791](#).
- [Memory hints and barriers on page F4-3802](#).
- [Barriers on page F4-3803](#).

The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as NOP.

K1.1.27 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DCCISW](#), [DCCSW](#), and [DCISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Note

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions [DC CISW](#), [DC CSW](#), and [DC ISW](#).

K1.1.28 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 System instructions.

———— Note —————

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

SRS (T32)

For a description of this instruction and the encoding, see [SRS](#), [SRSDA](#), [SRSDDB](#), [SRSIA](#), [SRSIB](#) on page F5-4292.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
 - R13 of the current mode is used.
 - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SRS (A32)

For a description of this instruction and the encoding, see [SRS](#), [SRSDA](#), [SRSDDB](#), [SRSIA](#), [SRSIB](#) on page F5-4292.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
 - R13 of the current mode is used.
 - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see the exception return form of [SUB](#), [SUBS \(immediate\)](#) on page F5-4394.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.

- If the instruction transfers an illegal mode encoding to [PSTATE.M](#), then this invokes the illegal exception return.

———— **Note** —————

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

For encoding T5:

- If `hw2[3:0]` are `0b1110`, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction is treated as a NOP.
 - The instruction is treated as if `hw2[3:0]` are `0b1110`.
 - The program counter is set using the value in the register specified by `hw2[3:0]`.

SUBS PC, LR and related instructions (A32)

For a description of this instruction and the encoding, see the exception return forms of [MOV, MOVS \(register\)](#) on page F5-4081 and [SUB, SUBS \(immediate\)](#) on page F5-4394.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to [PSTATE.M](#), then this invokes the illegal exception return.

———— **Note** —————

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

K1.1.29 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in [Alphabetical list of Advanced SIMD and floating-point instructions on page F6-4520](#).

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see [VCVT \(between floating-point and fixed-point, floating-point\) on page F6-4677](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see [VLD1 \(multiple single elements\) on page F6-4763](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see [VLD1 \(single element to all lanes\) on page F6-4760](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see [VLD2 \(multiple 2-element structures\) on page F6-4780](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to one lane\) on page F6-4771](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to all lanes\)](#) on page F6-4777.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (multiple 3-element structures)

For a description of this instruction and the encoding, see [VLD3 \(multiple 3-element structures\)](#) on page F6-4794.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to one lane)

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to one lane\)](#) on page F6-4785.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to all lanes\)](#) on page F6-4791.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (multiple 4-element structures)

For a description of this instruction and the encoding, see [VLD4 \(multiple 4-element structures\)](#) on page F6-4806.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to one lane)

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to one lane\)](#) on page F6-4797.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to all lanes\)](#) on page F6-4803.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLDM

For a description of this instruction and the encoding, see [VLDM, VLDMDB, VLDMIA](#) on page F6-4809.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMOV (between two general-purpose registers and two single-precision registers)

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and two single-precision registers\)](#) on page F6-4885.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMOV (between two general-purpose registers and a doubleword floating-point register)

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and a doubleword floating-point register\)](#) on page F6-4864.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST1 (multiple single elements)

For a description of this instruction and the encoding, see [VST1 \(multiple single elements\)](#) on page F6-5126.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (multiple 2-element structures)

For a description of this instruction and the encoding, see [VST2 \(multiple 2-element structures\)](#) on page F6-5140.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (single 2-element structure from one lane)

For a description of this instruction and the encoding, see [VST2 \(single 2-element structure from one lane\)](#) on page F6-5134.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (multiple 3-element structures)

For a description of this instruction and the encoding, see [VST3 \(multiple 3-element structures\)](#) on page F6-5151.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (single 3-element structure from one lane)

For a description of this instruction and the encoding, see [VST3 \(single 3-element structure from one lane\)](#) on page F6-5145.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (multiple 4-element structures)

For a description of this instruction and the encoding, see [VST4 \(multiple 4-element structures\)](#) on page F6-5160.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (single 4-element structure from one lane)

For a description of this instruction and the encoding, see [VST4 \(single 4-element structure from one lane\)](#) on page F6-5154.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VSTM

For a description of this instruction and the encoding, see [VSTM, VSTMDB, VSTMIA](#) on page F6-5163.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

K1.1.30 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- *Misprogramming VTCR.S.*
- *Misprogramming VTCR.{SL0, T0SZ}.*

Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the ARMv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

————— Note —————

The CONSTRAINED UNPREDICTABLE behavior described in *Misprogramming VTCR.{SL0, T0SZ}* means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.31 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- *ERET in User mode or System mode.*
- *Accessing Hyp mode from outside Hyp mode.*
- *Modifying PSTATE.M when in Hyp mode on page K1-7214.*
- *Use of Hyp mode in Secure state on page K1-7214.*
- *Execution of Load/Store unprivileged instructions in Hyp mode on page K1-7214.*
- *Exception return to Hyp mode on page K1-7214.*
- *Accessing registers that cannot be accessed using MSR/MRS instructions on page K1-7214.*
- *Memory type handling on page K1-7215.*
- *Hyp mode TLB maintenance instructions on page K1-7215.*
- *Hyp mode VA to PA address translation instructions on page K1-7215.*
- *Stage 1 default memory type on page K1-7215.*
- *Trapping of general exceptions to Hyp mode on page K1-7215.*
- *Prevention of rootkits using Hyp mode or Secure state on page K1-7216.*
- *HVC on page K1-7216.*
- *MSR (banked register) and MRS (banked register) on page K1-7216.*

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in *SUBS PC, LR and related instructions (T32) on page K1-7207.*

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32) on page K1-7207* and *SRS (A32) on page K1-7207.*

Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-7207](#) and [SRS \(A32\) on page K1-7207](#).

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-7207](#) and [SRS \(A32\) on page K1-7207](#).

Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the ARMv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

```
MSR <Rm>_<mode>, <Rn>
MSR SPSR_<mode>, <Rn>
MSR ELR_hyp, <Rn>
MRS <Rn>, <Rm>_<mode>
MRS <Rn>, SPSR_<mode>
MRS <Rn>, ELR_hyp
```

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MRS instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.

Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

Hyp mode TLB maintenance instructions

If a [TLBIMVAH](#), [TLBIMVALH](#), [TLBIMVAHIS](#), [TLBIMVALHIS](#), [TLBIALLH](#), [TLBIALLHIS](#), [TLBIALLNSNH](#), [TLBIALLNSNHIS](#), [TLBIIPAS2](#), [TLBIIPAS2L](#), [TLBIIPAS2IS](#), or [TLBIIPAS2LIS](#) instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executed as if it had been executed in Monitor mode.

For more information about these instructions see [The scope of TLB maintenance instructions on page G5-5538](#).

Hyp mode VA to PA address translation instructions

If an [ATS1HR](#) or [ATS1HW](#) instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executed as if it had been executed in Monitor mode.

For more information about these instructions see [Address translation instruction naming and operation summary on page G5-5577](#).

Stage 1 default memory type

If $HCR.DC == 1$, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- $SCTLR.M == 0$, regardless of the actual value of $SCTLR.M$, other than for the value returned by an explicit read of $SCTLR.M$.
- $HCR.VM == 1$, regardless of the actual value of $HCR.VM$, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when $HCR.TGE == 1$ invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when $HCR.TGE == 1$ by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting $PSTATE.IL$ to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when $HCR.TGE$ is set, by changing $SCR.NS$ from 0 to 1, results in no change of $SCR.NS$.

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when $HCR.TGE == 1$:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure $SCTLR.M$ is treated as being 0, regardless of its actual value, other than for an explicit read of this bit.
- $HCR.FMO$, $HCR.IMO$, and $HCR.AMO$ are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.

- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.

Prevention of rootkits using Hyp mode or Secure state

If an **HVC** instruction is executed in Hyp mode when **SCR.HCE** == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If an **SMC** instruction is executed in a Secure privileged mode when **SCR.SCD** == 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

HVC

For a description of this instruction and the encoding, see [HVC on page F5-3939](#).

For the A1 encoding, if cond field != 1110, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

MSR (banked register) and MRS (banked register)

[Encoding and use of banked register transfer instructions on page F5-4514](#) identifies cases where attempted execution of an MRS (banked register) or MSR (banked register) was UNPREDICTABLE in ARMv7 and becomes CONSTRAINED UNPREDICTABLE in ARMv8. This includes cases where:

- The target register specified by the {R, SYSm} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see [Usage restrictions on the banked register transfer instructions on page F5-4515](#).
- The instruction was executed specifying unallocated {R, SYSm} field values, see [Encoding the register argument in the banked register transfer instructions on page F5-4516](#).

If one of these encodings for an MSR (banked register) or MRS (banked register) instruction is executed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- An allocated MSR (banked register) or MRS (banked register) instruction is executed.

K1.1.32 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

———— **Note** —————

These constraints are identical to those for the equivalent AArch64 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7231.

K1.1.33 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-6427 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- [Overview of the constraints on AArch64 UNPREDICTABLE behaviors.](#)
- [SBZ or SBO fields in A64 instructions.](#)
- [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values.](#)
- [CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-7219.](#)
- [Translation table base address alignment on page K1-7220.](#)
- [The Performance Monitors Extension on page K1-7220.](#)
- [The Activity Monitors Extension on page K1-7221.](#)

- [Programming the CSSELR_EL1.Level for a cache level that is not implemented on page K1-7222.](#)
- [Crossing a page boundary with different memory types or Shareability attributes on page K1-7223.](#)
- [Crossing a peripheral boundary with a Device access on page K1-7223.](#)
- [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7223.](#)
- [CONSTRAINED UNPREDICTABLE behavior for A64 instructions on page K1-7224.](#)
- [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7231.](#)
- [Reserved values in System and memory-mapped registers and translation table entries on page K1-7231.](#)
- [CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-7232.](#)

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

————— **Note** —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

—————

K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO, as described in [Fixed values in AArch64 instruction and System register descriptions on page C2-165](#). Except for specific cases identified in [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7223](#), if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

K1.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes [ARMv8.2-TTCNP](#), this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting [TTBR.CnP](#) to 1, as identified in the descriptions of the [TTBR.CnP](#) field. In this case, for a particular [TTBR](#), the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that [TTBR](#) on one of the PEs within the Inner Shareable domain for which both the value of [TTBR.CnP](#) is 1 and the other conditions for sharing translation table entries pointed to by that [TTBR](#) are met.
- An amalgamation of the values of the translation table entries pointed to by that [TTBR](#) on two or more of the PEs within the Inner Shareable domain for which both the value of [TTBR.CnP](#) is 1 and the other conditions for sharing translation table entries pointed to by that [TTBR](#) are met.

———— **Note** —————

If the *Effective value* of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that *Effective value* must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a [TTBR.CnP](#) value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that [TTBR](#) and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see [TLB conflict aborts on page D5-2513](#).

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.2.5 Translation table base address alignment

In the translation table base registers `TTBR0_EL1`, `TTBR1_EL1`, `TTBR0_EL2`, `VTTBR_EL2`, and `TTBR0_EL3`, register bits[48:x] hold the translation table base address, where *x* depends on the translation table granule size and the size of the addressed translation table, as described in *Memory translation granule size on page D5-2406*.

Register bits[(x-1):0], unless redefined for another purpose, correspond to bits[(x-1):0] of the translation table base address and therefore are RES0.

Note

- When [ARMv8.2-LPA](#) is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
- When [ARMv8.2-TTCNP](#) is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(x-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
 - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate `TTBR.BADDR` field description.

K1.2.6 The Performance Monitors Extension

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If `PMSELR_EL0.SEL` is not equal to 31, and `PMSELR_EL0.SEL` is greater than or equal to `PMCR_EL0.N`, and the PE is executing in an Exception level in Secure state or in EL2.
- If `PMSELR_EL0.SEL` is not 31, and `PMSELR_EL0.SEL` is greater than or equal to `MDCR_EL2.HPMN`, and the PE is executing in an Exception level in Non-secure state other than in EL2.

In these cases, one of the following behaviors must occur:

- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state are UNDEFINED.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as RAZ/WI.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state execute as NOPs.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as if `PMSELR_EL0.SEL` contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as if `PMSELR_EL0.SEL` is 31.
- In Non-secure state, for an access to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from EL0 are permitted when:
 - EL1 is using AArch32 and the value of `PMUSERENR.EN` is 1.
 - EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

If `PMSELR_EL0.SEL` is equal to 31, then one of the following behaviors must occur:

- Accesses to `PMXVCNTR_EL0` are UNDEFINED.
- Accesses to `PMXVCNTR_EL0` behave as RAZ/WI.
- Accesses to `PMXVCNTR_EL0` execute as NOPs.

- Accesses to `PMXEVCNTR_EL0` behave as if `PMSELR_EL0.SEL` contains an unknown value that is less than the number of counters accessible at the current Exception level and Security state.

If `MDCR_EL2.HPMN` is set to 0, or to a value larger than `PMCR_EL0.N`, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of `MDCR_EL2.HPMN` is UNKNOWN.
- Either:
 - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if `MDCR_EL2.HPMN` is set to an UNKNOWN non-zero value less than `PMCR_EL0.N`.
 - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.2.7 The Activity Monitors Extension

If `<n>` is greater than the number of architected activity monitor event counters, reads and writes of `AMEVCNTR0<n>_EL0` and `AMEVTYPER0<n>_EL0` are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

———— **Note** —————

`AMCGCR_EL0.CG0NC` identifies the number of architected activity monitor event counters.

If `<n>` is greater than the number of auxiliary activity monitor event counters, reads and writes of `AMEVCNTR1<n>_EL0` and `AMEVTYPER1<n>_EL0` are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

———— **Note** —————

`AMCGCR_EL0.CG1NC` identifies the number of auxiliary activity monitor event counters.

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of `AMCNTENCLR1_EL0` and `AMCNTENSET0_EL0` are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

———— **Note** —————

The number of auxiliary activity monitor event counters implemented is zero exactly when `AMCFGR_EL0.NCG == 0b0000`.

K1.2.8 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, `ESR_ELx` is UNKNOWN.

———— **Note** ————

The value written to `ESR_ELx` must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.9 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an unknown address and the tags associated with address also become unknown.

———— **Note** ————

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address `0xFFFF FFFF FFFF FFFF` and the byte at virtual address `0x0000 0000 0000 0000`.

K1.2.10 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.2.11 Programming the `CSSELR_EL1.Level` for a cache level that is not implemented

If the `CSSELR_EL1.Level` is programmed to a cache level that is not implemented, then a read of `CSSELR_EL1` returns an UNKNOWN value in `CSSELR_EL1.Level`.

If `CSSELR_EL1.Level` is programmed to a cache level that is not implemented, then on a read of `CCSIDR_EL1` an implementation must perform one of the following behaviors:

- The `CCSIDR_EL1` read is treated as a NOP.
- The `CCSIDR_EL1` read is UNDEFINED.
- The `CCSIDR_EL1` read returns an UNKNOWN value.

When ARMv8.3-CCIDX is implemented, `CCSIDR2_EL1` is implemented. If `CSSELR_EL1.Level` is programmed to a cache level that is not implemented, then on a read of `CCSIDR2_EL1` an implementation must perform one of the following behaviors:

- The `CCSIDR2_EL1` read is treated as a NOP.
- The `CCSIDR2_EL1` read is UNDEFINED.
- The `CCSIDR2_EL1` read returns an UNKNOWN value.

K1.2.12 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.
For the Non-secure EL1&0 translation regime:
 - If the stage 1 translation generated the mismatch then the resulting exception is taken to EL1.
 - If the stage 2 translation generated the mismatch then the resulting exception is taken to EL2.
 - If both stages of translation generate the mismatch then the exception can be taken to either EL1 or EL2.
- The instruction executes as a NOP.

K1.2.13 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an alignment fault caused by the memory type.
For the Non-secure EL1&0 translation regime:
 - If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
 - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
 - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.
- The instruction executes as a NOP.

———— **Note** —————

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

K1.2.14 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-141 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a StoreExcl instruction is different from the virtual address of the preceding LoadExcl instruction in the same thread of execution.

- The transaction size of a StoreExc1 instruction is different from the transaction size of the preceding LoadExc1 instruction in the same thread of execution.
- The StoreExc1 instruction accesses a different number of registers than the preceding LoadExc1 instruction in the same thread of execution.
- The memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, either:
 - Because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction.
 - Because the LoadExc1 instruction and the StoreExc1 instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page B2-141 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

K1.2.15 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in [Chapter C6 A64 Base Instruction Descriptions](#) and [Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions](#).

LDAXP

For a description of this instruction and the encoding, see [LDAXP](#) on page C6-867.

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP

For a description of this instruction and the encoding, see [LDNP](#) on page C6-891.

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP (SIMD&FP)

For a description of this instruction and the encoding, see [LDNP \(SIMD&FP\)](#) on page C7-1674.

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDP

For a description of this instruction and the encoding, see [LDP on page C6-893](#).

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \parallel t2 == n) \&\& n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDP (SIMD&FP)

For a description of this instruction and the encoding, see [LDP \(SIMD&FP\) on page C7-1676](#).

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDPSW

For a description of this instruction and the encoding, see [LDPSW on page C6-896](#).

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \parallel t2 == n) \&\& n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDR (immediate)

For a description of this instruction and the encoding, see [LDR \(immediate\)](#) on page C6-899.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRB (immediate)

For a description of this instruction and the encoding, see [LDRB \(immediate\)](#) on page C6-908.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRH (immediate)

For a description of this instruction and the encoding, see [LDRH \(immediate\)](#) on page C6-912.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSB (immediate)

For a description of this instruction and the encoding, see [LDRSB \(immediate\)](#) on page C6-916.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see [LDRSH \(immediate\)](#) on page C6-921.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see [LDRSW \(immediate\)](#) on page C6-926.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see [LDXP](#) on page C6-987.

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

STP

For a description of this instruction and the encoding, see [STP on page C6-1144](#).

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \ || \ t2 == n) \ \&\& \ n \ != \ 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STLXP

For a description of this instruction and the encoding, see [STLXP on page C6-1133](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t \ || \ (s == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \ != \ 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STLXR

For a description of this instruction and the encoding, see [STLXR on page C6-1136](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \ != \ 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STLXRB

For a description of this instruction and the encoding, see [STLXRB](#) on page C6-1138.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STLXRH

For a description of this instruction and the encoding, see [STLXRH](#) on page C6-1140.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STR (immediate)

For a description of this instruction and the encoding, see [STR \(immediate\)](#) on page C6-1147.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STRB (immediate)

For a description of this instruction and the encoding, see [STRB \(immediate\)](#) on page C6-1152.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (immediate)

For a description of this instruction and the encoding, see [STRH \(immediate\)](#) on page C6-1156.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STXP

For a description of this instruction and the encoding, see [STXP](#) on page C6-1200.

CONSTRAINED UNPREDICTABLE behavior

If $s == t \ || \ (s == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \neq 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STXR

For a description of this instruction and the encoding, see [STXR](#) on page C6-1203.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \neq 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STXRB

For a description of this instruction and the encoding, see [STXRB](#) on page C6-1205.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \neq 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STXRH

For a description of this instruction and the encoding, see [STXRH on page C6-1207](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \neq 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

K1.2.16 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DC CISW](#), [DC CSW](#), and [DC ISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Note

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions [DCCISW](#), [DCCSW](#), and [DCISW](#).

K1.2.17 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

———— **Note** —————

These constraints are identical to those for the equivalent AArch32 definitions, as given in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-7216.

K1.2.18 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state on page H2-6427](#) of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

Appendix K2

Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- [About the recommended external debug interface on page K2-7234.](#)
- [PMUEVENT bus on page K2-7238.](#)
- [Recommended authentication interface on page K2-7239.](#)
- [Management registers and CoreSight compliance on page K2-7241.](#)

———— **Note** ————

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of ARM products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

K2.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection.

[Table K2-1](#) shows the signals in the recommended interface.

Table K2-1 Recommended debug interface signals

Name	Direction	Description	Notes
DBGGEN	In	External debug enable	-
SPIDEN	In	Secure privileged external debug enable	-
		Secure privileged self-hosted debug enable	Only in Secure AArch32 modes when enabled by MDCR_EL3.SPD32
NIDEN	In	External profiling and trace enable	If ARMv8.4-Debug is implemented, this signal is not implemented.
SPNIDEN	In	Secure external profiling and trace enable	If ARMv8.4-Debug is implemented, this signal is not implemented.
EDBGRQ	In	External halt request	IMPLEMENTATION DEFINED mechanism to halt the PE. See EDBGRQ and DBGACK on page K2-7237.
DBGACK	Out	Debug Acknowledge	Indicate to the system that a PE is in Debug state. See EDBGRQ and DBGACK on page K2-7237.
COMMIRQ	Out	DCC interrupt	Interface to an interrupt controller. See Interrupt-driven use of the DCC on page H4-6498 and the pseudocode for function CheckForDCCInterrupts() .
PMUIRQ	Out	Performance Monitor overflow	Interface to an interrupt controller. See Behavior on overflow on page D6-2542.
COMMRX	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See Interrupt-driven use of the DCC on page H4-6498 and the pseudocode for function CheckForDCCInterrupts() .
COMMTX	Out	DTRTX is empty	
PMUEVENT[n:0]	Out	Performance Monitors event bus	See PMUEVENT bus on page K2-7238.
DBGNOPWRDWN	Out	Core no powerdown request	Interface to a power controller. See DBGPRCR_EL1.CORENPDRQ .
DBGPWRUPREQ	Out	Core powerup request	Interface to a power controller. See EDPRCR.COREPURQ .
DBGRSTREQ	Out	Warm reset request	Interface to a power controller. See EDPRCR.CWRR .
DBGBUSCANCELREQ	Out	All asynchronous entry to Debug state	Extension to the bus interface. See EDRCR.CBRRQ .

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
DBGPWRDUP	In	Core powerup status	Interface to a power controller. See EDPRSR.PU .
DBGROMADDR[n:12]	In	MDRAR_EL1 .ROMADDR	<i>n</i> depends on the size of the physical address space.
DBGROMADDRV	In	MDRAR_EL1 .Valid	-
PRESETDBG	In	External debug reset	-
CPUPORSET	In	Cold reset	-
CORERESET	In	Warm reset	-
PSELDBG	In	Debug APB slave port	For details see <i>AMBA APB3</i> . ARM recommends a single slave port for all integrated debug components. PADDRDBG31 distinguishes memory-mapped and Debug Access Port accesses: 0 Memory-mapped access 1 Debug Access Port access If ARMv8.4-Debug is implemented, PPROT[1] distinguishes between Secure and Non-secure accesses.
PENABLEDBG	In		
PWRITEDBG	In		
PRDATADBG[31:0]	Out		
PWDATADBG[31:0]	In		
PADDRDBG[n:2] ^a	In		
PREADYDBG	Out		
PSLVERRDBG	Out		
PCLKDBG	In		
PCLKENDBG	In		
PPROT[1]	In		
CTICHIN	In	CoreSight channel interface	For details, see the <i>ARM® CoreSight™ Architecture Specification</i> . The ACK signals are not required if the channel interface is synchronous.
CTICHOUTACK	In		
CTICHOUT	Out		
CTICHINACK	Out		
CTIIRQ	Out	CTI interrupt, see Description and allocation of CTI triggers on page H5-6509	Implements a handshake for an edge-sensitive interrupt.
CTIIRQACK	In		

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
ATDATA[nx8-1:0]	Out	AMBA 4 ATB interface	For details, see the <i>AMBA 4 ATB Protocol Specification, ATBv1.0 and ATBv1.1</i> . Only available if the OPTIONAL Trace extension is implemented.
ATBYTES[n-1:0]	Out		
ATID[6:0]	Out		
ATREADY	In		
ATVALID	Out		
AFREADY	Out		
AFVALID	Out		
SYNCREQ	In		
ATCLK	In		
ATCLKEN	In		
ATRESET	In		

a. The value of n depends on the size of the address space occupied by the Debug port.

Figure K2-1 shows the recommended debug interface.

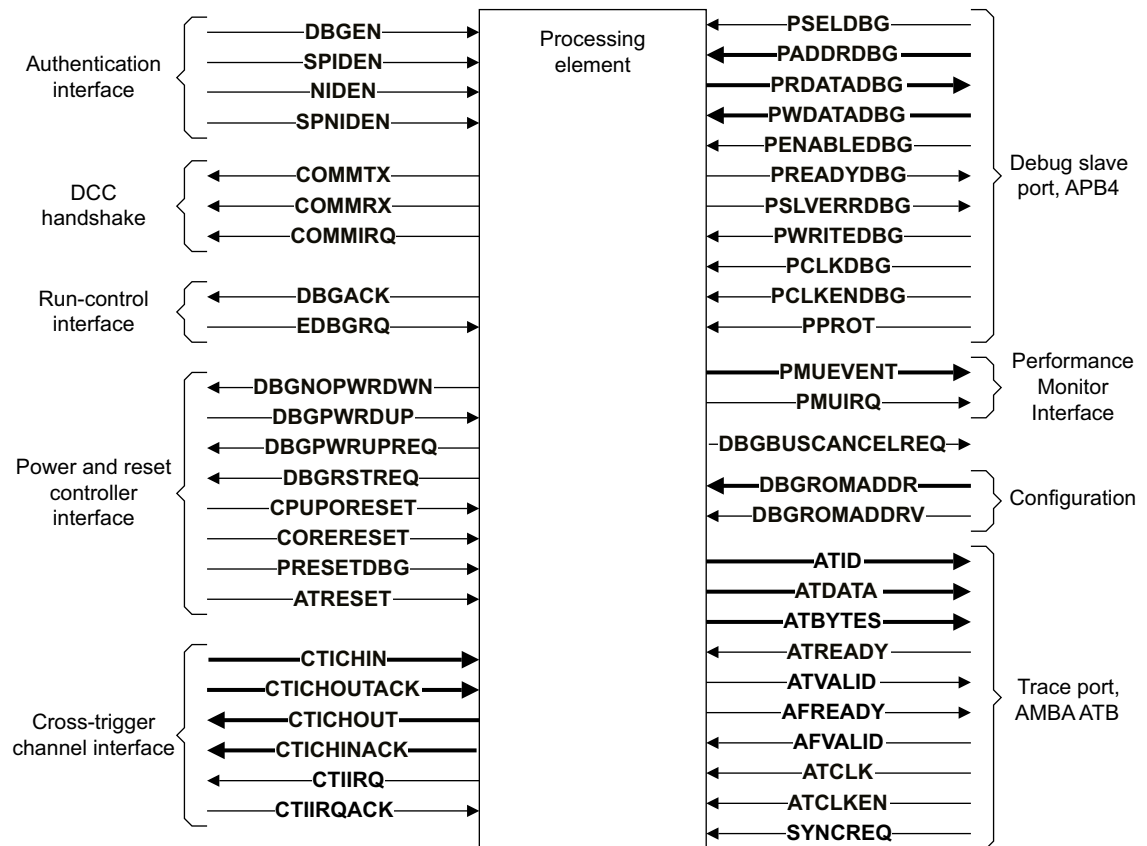

Figure K2-1 Recommended external debug interface, including the APB3 slave port

K2.1.1 EDBGRRQ and DBGACK

EDBGRQ is an IMPLEMENTATION DEFINED means of generating the External Debug Request debug event described in *External Debug Request debug event* on page H3-6473.

The PE asserts **DBGACK** when the PE is in Debug state. The PE might also include variants of this signal:

DBGTRIGGER

Asserted by the PE when it commits to entering Debug state.

DBGCPUDONE

Asserted by the PE when it has completed all Non-debug state memory accesses and Debug state entry is complete. **DBGCPUDONE** indicates that memory accesses issued by the PE result from operations originating from debugger commands.

In previous architecture versions, these signals provide an interface between the PE and cross-trigger logic. In ARMv8, the architectural Cross-Trigger Interface provides this functionality for external debuggers.

K2.1.2 Secure and Non-secure views of the debug registers

If [ARMv8.4-Debug](#) is implemented, the external debug interface has views of Secure and Non-secure debug registers. The DAP must ensure that accesses are made only when permitted. The ARM debug interface describes a standard APB-AP programmers model for APB4 which signals Secure and Non-secure accesses on the **PPROT[1]** signal, and is recommended for new designs.

If [ARMv8.4-Debug](#) is implemented, and an APB-AP implements an APB3 master port, which does not support Secure and Non-secure views, ARM recommends that the following is implemented:

- If **SPIDEN** is HIGH and **DBGGEN** is HIGH, all external debug accesses are treated as Secure.
- If either **SPIDEN** is LOW or **DBGGEN** is LOW, all external debug accesses are treated as Non-secure.

If the PE APB slave port is APB4, this might be implemented by, for example, fixing **PPROT[1]** to the inverse of (**SPIDEN & DBGGEN**) when bridging from APB3 to APB4.

K2.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
 - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
 - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
 - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSELR multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact ARM.

K2.3 Recommended authentication interface

An implementation of the ARMv8 architecture must support debug authentication described in [Required debug authentication on page H1-6414](#).

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but ARM recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.

If [ARMv8.4-Debug](#) is not implemented, ARM also recommends using the following signals:

- **NIDEN**.
- **SPNIDEN**.

ARM recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and `SDCR.SPD == 0b00`.
- Secure EL1 is using AArch32 and `MDCR_EL3.SPD32 == 0b00`.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

If [ARMv8.4-Debug](#) and CoreSight ETR are both implemented, the ETR has an independent **DBGEN** signal that must be tied HIGH to enable self-hosted use of trace.

[Table K2-2](#) shows the debug authentication pseudocode functions and the recommended implementations.

Table K2-2 Recommended implementation of debug enable pseudocode functions

Pseudocode function	Description	Implementation
<code>AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</code>	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	(DBGEN AND SPIDEN)
<code>ExternalSecureNoninvasiveDebugEnabled()</code> ^a	Secure non-invasive debug enabled	(DBGEN OR NIDEN^b AND (SPIDEN OR SPNIDEN^c)
<code>ExternalSecureInvasiveDebugEnabled()</code>	Secure invasive debug enabled	(DBGEN AND SPIDEN)
<code>ExternalNoninvasiveDebugEnabled()</code> ^d	Non-secure non-invasive debug enabled	(DBGEN OR NIDEN^b)
<code>ExternalInvasiveDebugEnabled()</code>	Non-secure invasive debug enabled	DBGEN

a. If [ARMv8.4-Debug](#) is implemented, `ExternalSecureNoninvasiveDebugEnabled() == ExternalSecureInvasiveDebugEnabled()`.

b. If [ARMv8.4-Debug](#) is implemented, the **NIDEN** signal is not implemented.

c. If [ARMv8.4-Debug](#) is implemented, the **SPNIDEN** signal is not implemented.

d. If [ARMv8.4-Debug](#) is implemented, `ExternalNoninvasiveDebugEnabled() == TRUE`.

The Debug_authentication() pseudocode function on [shared/debug](#) on page J1-7086 defines the authentication signals DBGEN, SPIDEN, NIDEN and SPNIDEN.

K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

K2.4.1 CoreSight interface register map

Table K2-3 shows the external management register maps for the following registers:

- ED** These are the external debug register.
- CTI** These are the Cross-trigger interface registers.
- PMU** These are the Performance Monitors registers.

Table K2-3 CoreSight interface register map

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xF00	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
0xF04-0xF9C	-	-	-	Reserved, RES0
0xFA0	DBGCLAIMSET_EL1 ^a	CTICLAIMSET ^b	-	CLAIM Tag Set registers
0xFA4	DBGCLAIMCLR_EL1 ^a	CTICLAIMCLR ^b	-	CLAIM Tag Clear registers
0xFA8	EDDEVAFF0 ^a	CTIDEVAFF0 ^c	PMDEVAFF0	Device Affinity registers
0xFAC	EDDEVAFF1 ^a	CTIDEVAFF1 ^c	PMDEVAFF1	
0xFB0	EDLAR ^d	CTILAR ^d	PMLAR ^d	Lock Access register
0xFB4	EDLSR ^d	CTILSR ^d	PMSLR ^d	Lock Status register
0xFB8	DBGAUTHSTATUS_EL1 ^a	CTIAUTHSTATUS	PMAUTHSTATUS	Authentication Status register
0xFBC	EDDEVARCH	CTIDEVARCH	PMDEVARCH	Device Architecture register
0xFC0	EDDEVID2 ^a	CTIDEVID2 ^a	-	Device ID register
0xFC4	EDDEVID1 ^a	CTIDEVID1 ^a	-	
0xFC8	EDDEVID ^a	CTIDEVID ^a	PMDEVID ^{a, e}	
0xFCC	EDDEVTYPE	CTIDEVTYPE	PMDEVTYPE	Device Type register
0xFD0	EDPIDR4	CTIPIDR4	PMPIDR4	Peripheral ID registers
0xFD4-0xFDC	-	-	-	Reserved, RES0
0xFE0	EDPIDR0	CTIPIDR0	PMPIDR0	Peripheral ID registers
0xFE4	EDPIDR1	CTIPIDR1	PMPIDR1	
0xFE8	EDPIDR2	CTIPIDR2	PMPIDR2	
0xFEC	EDPIDR3	CTIPIDR3	PMPIDR3	

Table K2-3 CoreSight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

- This register must always be implemented, regardless of whether the component is CoreSight compliant.
- If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
- If the CTI implements CTIV1, this register is not implemented. See the register description for details.
- The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.
- PMDEVID is implemented only from ARMv8.2 or if ARMv8.2-PCSample is implemented, otherwise its offset is RES0.

K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, [Table K2-4 on page K2-7243](#), [Table K2-5 on page K2-7244](#), and [Table K2-6 on page K2-7245](#) show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see [External debug interface register access permissions summary on page H8-6547](#).

———— Note —————

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

[Table K2-4 on page K2-7243](#), [Table K2-5 on page K2-7244](#), and [Table K2-6 on page K2-7245](#) include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in [Reserved and unallocated registers on page H8-6547](#) does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses on page H8-6542](#).

When `HaveSecureExtDebugView() == TRUE`, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

The terms in [Table K2-4 on page K2-7243](#), [Table K2-5 on page K2-7244](#), and [Table K2-6 on page K2-7245](#) are defined as follows:

Domain	This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.
Conditions	This lists the conditions under which the access is attempted. To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true. The conditions are: Off <code>EDPRSR.PU == 0</code> . The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

- DLK** If the OS Double Lock is implemented and `DoubleLockStatus() == TRUE`. The OS Double Lock is locked.
- OSLK** `OSLSR.OSLK == 1`. The OS Lock is locked.
- Default** This provides the default access permissions, if there are no conditions that prevent access to the register.
- SLK** This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See [Register access permissions for memory-mapped accesses on page H8-6542](#). For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.
- RO** This means that the register or field is read-only.
- RW** This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.
- RC** This means that the bit clears to 0 after a read.
- (SE)** This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.
- WO** This means that the register or field is write-only.
- WI** This means that the register or field ignores writes.
- IMP DEF** This means that the access permissions are IMPLEMENTATION DEFINED.

Table K2-4 External debug interface access permissions, CoreSight registers (debug)

Offset	Register	Domain	Conditions (priority left to right)			Default	SLK

a. Implemented from ARMv8.2, or if [ARMv8.2-PCSample](#) is implemented. Otherwise this location is RES0.

K2.4.3 Management register resets

[Table K2-7](#) shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

[Table K2-7](#) shows a summary of the management register resets.

Table K2-7 Management register resets

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1	Cold reset	CLAIM	0x00	CLAIM tags
CTICLAIMCLR	External debug	CLAIM	0x00000000	
CTILSR ^a EDLSR ^a PMLSR ^a	External debug	SLK	1	Software Lock

a. Only if the OPTIONAL Software Lock is implemented

K2.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the *ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2*, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the *ARM® CoreSight™ Architecture Specification*.

Table K2-8 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

Table K2-8 Peripheral Identification Registers

Register offset	Description	Reference		
		External Debug	CTI	Performance Monitors
0xFD0	Peripheral ID4	EDPIDR4	CTIPIDR4	PMPIDR4
0xFD4	Reserved for Peripheral ID5	-	-	-
0xFD8	Reserved for Peripheral ID6	-	-	-
0xFDC	Reserved for Peripheral ID7	-	-	-
0xFE0	Peripheral ID0	EDPIDR0	CTIPIDR0	PMPIDR0
0xFE4	Peripheral ID1	EDPIDR1	CTIPIDR1	PMPIDR1
0xFE8	Peripheral ID2	EDPIDR2	CTIPIDR2	PMPIDR2
0xFEC	Peripheral ID3	EDPIDR3	CTIPIDR3	PMPIDR3

Figure K2-2 shows the register field allocation scheme for the Peripheral ID Registers.

Figure K2-2 Peripheral ID register format

Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K2-3.

Figure K2-3 Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value

Figure K2-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:

- Have fixed values, including the bits that are reserved.
- Have fixed values in an implementation that is designed by ARM.

For more information about the fields and their values see Table K2-9 on page K2-7248.

Figure K2-4 Peripheral ID fields, with values for a implementation designed by ARM

Table K2-9 shows the fields in the Peripheral ID.

Table K2-9 Fields in the Peripheral Identification Registers

Name	Size	Description	Registers
4KB count	4 bits	Log2 of the number of 4KB blocks occupied by the implementation.	EDPIDR4 CTIPIDR4 PMPIDR4
JEP106 code	4+7 bits	Identifies the designer of the implementation. This value consists of: <ul style="list-style-type: none"> A 4-bit continuation code, also described as the bank number. A 7-bit identification code. For implementations designed by ARM, the continuation code is 0x4, indicating bank 5, and the identity code is 0x3B.	EDPIDR1, EDPIDR2, EDPIDR4 CTIPIDR1, CTIPIDR2, CTIPIDR4 PMPIDR1, PMPIDR2, PMPIDR4
RevAnd	4 bits	Manufacturing revision number. Indicates a late modification to the implementation, usually as a result of an <i>Engineering Change Order</i> (ECO). This field starts at 0x0 and is incremented by the integrated circuit manufacturer on metal fixes.	EDPIDR3 CTIPIDR3 PMPIDR3
Customer modified	4 bits	Indicates an endorsed modification to the implementation. If the system designer cannot modify the implementation supplied by the implementation designer then this field is RES0.	EDPIDR3 CTIPIDR3 PMPIDR3
Revision	4 bits	Revision number for the implementation. Starts at 0x0 and increments by 1 at both major and minor revisions.	EDPIDR2 CTIPIDR2 PMPIDR2
Uses JEP106 ID code	1 bit	This bit is set to 1 when a JEP106 identification code is used. This bit must be 1 on all ARMv8 implementations.	EDPIDR2 CTIPIDR2 PMPIDR2
Part number	12 bits	Part number for the implementation. Each organization designing to the ARM Debug architecture specification keeps its own part number list.	EDPIDR0, EDPIDR1 CTIPIDR0, CTIPIDR1 PMPIDR0, PMPIDR1

A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.

- RevAnd.

For components with a *Component class* of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight *Device type*. However, ARM strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see [About the Component Identification scheme](#).
- About the CoreSight Device type, see [EDDEVTYPE](#), [CTIDEVTYPE](#), or [PMDEVTYPE](#).
- About CoreSight components and their identification, see the *ARM® Debug Interface Architecture Specification*.

Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is IMPLEMENTATION DEFINED, with the following set of restrictions so that:

- The REVISION field must increase monotonically with revisions.

———— **Note** —————

ARM recommends that the REVISION field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The REVAND field should increase monotonically with revisions.

———— **Note** —————

ARM recommends that the REVAND field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The PART field must have a degree of uniqueness:

- Two component designs can have the same part number so long as they are sub-components of the same part and the programmers' model for the part has the means to disambiguate sub-components.
- Otherwise, two component designs must have unique part numbers.

The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.

A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

K2.4.5 About the Component Identification scheme

The Component Identification Registers identify the processor as an ARM Debug Interface v5 component. For more information, see the *ARM® Debug Interface Architecture Specification* and the *ARM® CoreSight™ Architecture Specification*.

The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

Table K2-10 Component Identification Registers

Register offset	Description	External debug	CTI	Performance Monitors
0xFF0	Component ID0	EDCIDR0	CTICIDR0	PMCIDR0
0xFF0	Component ID1	EDCIDR1	CTICIDR1	PMCIDR1
0xFF0	Component ID2	EDCIDR2	CTICIDR2	PMCIDR2
0xFF0	Component ID3	EDCIDR3	CTICIDR3	PMCIDR3

Figure K2-5 shows the register field allocation scheme for the Component ID Registers.

Figure K2-5 Component ID Register format

Software can consider the eight Component ID Registers as defining a single 32-bit Component ID, as shown in Figure K2-6.

Figure K2-6 Mapping between Component ID Registers and a 32-bit Component ID Value

Appendix K3

Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

- *ARM recommendations for IMPLEMENTATION DEFINED event numbers on page K3-7252.*
- *Summary of events for exceptions taken to an Exception level using AArch64 on page K3-7267.*

K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers

Event number	Event mnemonic	Description
0x0040	L1D_CACHE_RD	Attributable Level 1 data cache access, read
0x0041	L1D_CACHE_WR	Attributable Level 1 data cache access, write
0x0042	L1D_CACHE_REFILL_RD ^a	Attributable Level 1 data cache refill, read
0x0043	L1D_CACHE_REFILL_WR ^a	Attributable Level 1 data cache refill, write
0x0044	L1D_CACHE_REFILL_INNER	Attributable Level 1 data cache refill, inner
0x0045	L1D_CACHE_REFILL_OUTER	Attributable Level 1 data cache refill, outer
0x0046	L1D_CACHE_WB_VICTIM	Attributable Level 1 data cache Write-Back, victim
0x0047	L1D_CACHE_WB_CLEAN	Level 1 data cache Write-Back, cleaning and coherency
0x0048	L1D_CACHE_INVAL	Attributable Level 1 data cache invalidate
0x0049-0x004B	-	Reserved
0x004C	L1D_TLB_REFILL_RD ^a	Attributable Level 1 data TLB refill, read
0x004D	L1D_TLB_REFILL_WR ^a	Attributable Level 1 data TLB refill, write
0x004E	L1D_TLB_RD	Attributable Level 1 data or unified TLB access, read
0x004F	L1D_TLB_WR	Attributable Level 1 data or unified TLB access, write
0x0050	L2D_CACHE_RD	Attributable Level 2 data cache access, read
0x0051	L2D_CACHE_WR	Attributable Level 2 data cache access, write
0x0052	L2D_CACHE_REFILL_RD ^a	Attributable Level 2 data cache refill, read
0x0053	L2D_CACHE_REFILL_WR ^a	Attributable Level 2 data cache refill, write
0x0054-0x0055	-	Reserved
0x0056	L2D_CACHE_WB_VICTIM	Attributable Level 2 data cache Write-Back, victim
0x0057	L2D_CACHE_WB_CLEAN	Level 2 data cache Write-Back, cleaning and coherency
0x0058	L2D_CACHE_INVAL	Attributable Level 2 data cache invalidate
0x0059-0x005B	-	Reserved
0x005C	L2D_TLB_REFILL_RD ^a	Attributable Level 2 data or unified TLB refill, read
0x005D	L2D_TLB_REFILL_WR ^a	Attributable Level 2 data or unified TLB refill, write

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x005E	L2D_TLB_RD	Attributable Level 2 data or unified TLB access, read
0x005F	L2D_TLB_WR	Attributable Level 2 data or unified TLB access, write
0x0060	BUS_ACCESS_RD	Bus access, read
0x0061	BUS_ACCESS_WR	Bus access, write
0x0062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable
0x0063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable
0x0064	BUS_ACCESS_NORMAL	Bus access, normal
0x0065	BUS_ACCESS_PERIPH	Bus access, peripheral
0x0066	MEM_ACCESS_RD	Data memory access, read
0x0067	MEM_ACCESS_WR	Data memory access, write
0x0068	UNALIGNED_LD_SPEC	Unaligned access, read
0x0069	UNALIGNED_ST_SPEC	Unaligned access, write
0x006A	UNALIGNED_LDST_SPEC	Unaligned access
0x006B	-	Reserved
0x006C	LDREX_SPEC	Exclusive operation speculatively executed, LDREX or LDX
0x006D	STREX_PASS_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x006E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, STREX or STX fail
0x006F	STREX_SPEC	Exclusive operation speculatively executed, STREX or STX
0x0070	LD_SPEC	Operation speculatively executed, load
0x0071	ST_SPEC	Operation speculatively executed, store
0x0072	LDST_SPEC	Operation speculatively executed, load or store
0x0073	DP_SPEC	Operation speculatively executed, integer data processing
0x0074	ASE_SPEC	Operation speculatively executed, Advanced SIMD instruction
0x0075	VFP_SPEC	Operation speculatively executed, floating-point instruction
0x0076	PC_WRITE_SPEC	Operation speculatively executed, software change of the PC
0x0077	CRYPTO_SPEC	Operation speculatively executed, Cryptographic instruction
0x0078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch
0x0079	BR_RETURN_SPEC	Branch speculatively executed, procedure return
0x007A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch
0x007B	-	Reserved
0x007C	ISB_SPEC	Barrier speculatively executed, ISB
0x007D	DSB_SPEC	Barrier speculatively executed, DSB

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x007E	DMB_SPEC	Barrier speculatively executed, DMB
0x007F-0x0080	-	Reserved
0x0081	EXC_UNDEF	Exception taken, Other synchronous
0x0082	EXC_SVC	Exception taken, Supervisor Call
0x0083	EXC_PABORT	Exception taken, Instruction Abort
0x0084	EXC_DABORT	Exception taken, Data Abort and SError
0x0085	-	Reserved
0x0086	EXC_IRQ	Exception taken, IRQ
0x0087	EXC_FIQ	Exception taken, FIQ
0x0088	EXC_SMC	Exception taken, Secure Monitor Call
0x0089	-	Reserved
0x008A	EXC_HVC	Exception taken, Hypervisor Call
0x008B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not <i>Taken locally</i> ^b
0x008C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not <i>Taken locally</i> ^b
0x008D	EXC_TRAP_OTHER	Exception taken, Other traps not <i>Taken locally</i> ^b
0x008E	EXC_TRAP_IRQ	Exception taken, IRQ not <i>Taken locally</i> ^b
0x008F	EXC_TRAP_FIQ	Exception taken, FIQ not <i>Taken locally</i> ^b
0x0090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire
0x0091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release
0x0092-0x009F	-	Reserved
0x00A0	L3D_CACHE_RD	Attributable Level 3 data or unified cache access, read
0x00A1	L3D_CACHE_WR	Attributable Level 3 data or unified cache access, write
0x00A2	L3D_CACHE_REFILL_RD ^a	Attributable Level 3 data or unified cache refill, read
0x00A3	L3D_CACHE_REFILL_WR ^a	Attributable Level 3 data or unified cache refill, write
0x00A4-0x00A5	-	Reserved
0x00A6	L3D_CACHE_WB_VICTIM	Attributable Level 3 data or unified cache Write-Back, victim
0x00A7	L3D_CACHE_WB_CLEAN	Attributable Level 3 data or unified cache Write-Back, cache clean
0x00A8	L3D_CACHE_INVALID	Attributable Level 3 data or unified cache access, invalidate

a. For more information, see [Relationship between REFILL events and associated access events on page K3-7265](#).

b. The [Glossary](#) defines the term *Taken locally*. See also [Exception levels on page D1-2146](#) for more information.

0x0040, L1D_CACHE_RD, Attributable Level 1 data cache access, read

This event is similar to Level 1 data cache access, [L1D_CACHE](#), but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

0x0041, L1D_CACHE_WR, Attributable Level 1 data cache access, write

This event is similar to Level 1 data cache access, [L1D_CACHE](#), but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

0x0042, L1D_CACHE_REFILL_RD, Attributable Level 1 data cache refill, read

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x0043, L1D_CACHE_REFILL_WR, Attributable Level 1 data cache refill, write

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x0044, L1D_CACHE_REFILL_INNER, Attributable Level 1 data cache refill, inner

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

———— **Note** —————

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x0045, L1D_CACHE_REFILL_OUTER, Attributable Level 1 data cache refill, outer

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x0046, L1D_CACHE_WB_VICTIM, Attributable Level 1 data cache Write-Back, victim

This event is similar to Level 1 data cache Write-Back, [L1D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If [ARMv8.4-PMU](#) is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If [ARMv8.4-PMU](#) is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

0x0047, L1D_CACHE_WB_CLEAN, Level 1 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 1 data cache Write-Back, [L1D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

———— **Note** —————

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

0x0048, L1D_CACHE_INVAL, Attributable Level 1 data cache invalidate

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If [ARMv8.4-PMU](#) is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If [ARMv8.4-PMU](#) is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x004C, L1D_TLB_REFILL_RD, Attributable Level 1 data TLB refill, read

This event is similar to Level 1 data TLB refill, [L1D_TLB_REFILL](#), but the counter counts only memory-read operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x004D, L1D_TLB_REFILL_WR, Attributable Level 1 data TLB refill, write

This event is similar to Level 1 data TLB refill, [L1D_TLB_REFILL](#), but the counter counts only memory-write operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x004E, L1D_TLB_RD, Attributable Level 1 data or unified TLB access, read

This event is similar to Level 1 data or unified TLB access, [L1D_TLB](#), but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x004F, L1D_TLB_WR, Attributable Level 1 data or unified TLB access, write

This event is similar to Level 1 data or unified TLB access, [L1D_TLB](#), but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x0050, L2D_CACHE_RD, Attributable Level 2 data cache access, read

This event is similar to Attributable Level 2 data cache access, [L2D_CACHE](#), but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

0x0051, L2D_CACHE_WR, Attributable Level 2 data cache access, write

This event is similar to Attributable Level 2 data cache access, [L2D_CACHE](#), but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

0x0052, L2D_CACHE_REFILL_RD, Attributable Level 2 data cache refill, read

This event is similar to Attributable Level 2 data cache refill, [L2D_CACHE_REFILL](#), but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x0053, L2D_CACHE_REFILL_WR, Attributable Level 2 data cache refill, write

This event is similar to Attributable Level 2 data cache refill, [L2D_CACHE_REFILL](#), but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x0056, L2D_CACHE_WB_VICTIM, Attributable Level 2 data cache Write-Back, victim

This event is similar to Attributable Level 2 data cache Write-Back, [L2D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If [ARMv8.4-PMU](#) is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If [ARMv8.4-PMU](#) is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

0x0057, L2D_CACHE_WB_CLEAN, Level 2 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 2 data cache Write-Back, [L2D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted as IMPLEMENTATION DEFINED.

———— **Note** —————

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x0058, L2D_CACHE_INVAL, Attributable Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If [ARMv8.4-PMU](#) is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If [ARMv8.4-PMU](#) is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

———— **Note** —————

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x005C, L2D_TLB_REFILL_RD, Attributable Level 2 data or unified TLB refill, read

This event is similar to Attributable Level 2 data or unified TLB refill, [L2D_TLB_REFILL](#), but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x005D, L2D_TLB_REFILL_WR, Attributable Level 2 data or unified TLB refill, write

This event is similar to Attributable Level 2 data or unified TLB refill, [L2D_TLB_REFILL](#), but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also [Relationship between REFILL events and associated access events](#). on page K3-7265.

0x005E, L2D_TLB_RD, Attributable Level 2 data or unified TLB access, read

This event is similar to Attributable Level 2 data or unified TLB access, [L2D_TLB](#), but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x005F, L2D_TLB_WR, Attributable Level 2 data or unified TLB access, write

This event is similar to Attributable Level 2 data or unified TLB access, [L2D_TLB](#), but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x0060, BUS_ACCESS_RD, Bus access, read

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

0x0061, BUS_ACCESS_WR, Bus access, write

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

0x0062, BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

———— **Note** ————

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0063, BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

———— **Note** ————

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0064, BUS_ACCESS_NORMAL, Bus access, normal

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

0x0065, BUS_ACCESS_PERIPH, Bus access, peripheral

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

0x0066, MEM_ACCESS_RD, Data memory access, read

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only memory-read operations that the PE made.

0x0067, MEM_ACCESS_WR, Data memory access, write

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only memory-write operations made by the PE.

0x0068, UNALIGNED_LD_SPEC, Unaligned access, read

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x0069, UNALIGNED_ST_SPEC, Unaligned access, write

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006A, UNALIGNED_LDST_SPEC, Unaligned access

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006C, LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x006D, STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [LDREX_SPEC](#) event.

0x006E, STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [LDREX_SPEC](#) event.

0x006F, STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the [LDREX_SPEC](#) event.

ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the [LDREX_SPEC](#) event.

0x0070, LD_SPEC, Operation speculatively executed, load

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only memory-reading instructions, as defined by the [LD_RETIRED](#) event.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

0x0071, ST_SPEC, Operation speculatively executed, store

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only memory-writing instructions, as defined by the [ST_RETIRED](#) event.

The counter counts [DC ZVA](#) as a store operation.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

0x0072, LDST_SPEC, Operation speculatively executed, load or store

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only memory-reading instructions and memory-writing instructions, as defined by the [LD_RETIRED](#) and [ST_RETIRED](#) events.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

0x0073, DP_SPEC, Operation speculatively executed, integer data processing

This event is similar to Operation speculatively executed, [INST_SPEC](#), but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, [Data processing - immediate](#) on page C3-193 and [Data processing - register](#) on page C3-198.
- In AArch32 state, [Data-processing instructions](#) on page F1-3616.

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, [System register instructions](#) on page C3-172, [System instructions](#) on page C3-172, and [Hint instructions](#) on page C3-173.
- In AArch32 state, [PSTATE and banked register access instructions](#) on page F1-3624, [Banked register access instructions](#) on page F1-3624, [Miscellaneous instructions](#) on page F1-3629, other than ISB and preloads, and [System register access instructions](#) on page F1-3633, other than LDC and STC instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST_SPEC](#) event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
 - FMOV (general).

- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
 - DUP (general).
 - SMOV.
 - UMOV.
 - INS (general).
- For AArch32 state:
 - VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
 - VMRS.
 - VMSR.

0x0074, ASE_SPEC, Operation speculatively executed, Advanced SIMD

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in [Data processing - SIMD and floating-point on page C3-206](#).
- For AArch32 state, [Advanced SIMD data-processing instructions on page F1-3637](#).

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than PMULL, in AArch64 state.
- VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST_SPEC](#) event.

0x0075, VFP_SPEC, Operation speculatively executed, floating-point

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only floating-point data-processing instructions, see:

- In AArch64 state, only the scalar floating-point operations listed in [Data processing - SIMD and floating-point on page C3-206](#).

————— Note —————

This event does not count the SIMD floating-point operations listed in [Data processing - SIMD and floating-point on page C3-206](#).

- In AArch32 state, [Floating-point data-processing instructions on page F1-3647](#).

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
- In AArch32 state, VCVT<mode>(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST_SPEC](#) event.

0x0076, PC_WRITE_SPEC, Operation speculatively executed, software change of the PC

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see [Common event numbers on page D6-2558](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

See also [PC_WRITE_RETIRED](#).

0x0077, CRYPTO_SPEC, Operation speculatively executed, Cryptographic instruction

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only Cryptographic instructions, except PMULL and VMULL, see [The Cryptographic Extension on page C3-226](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

0x0078, BR_IMMED_SPEC, Branch speculatively executed, immediate branch

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see [Common event numbers on page D6-2558](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also [BR_IMMED_RETIRED](#).

0x0079, BR_RETURN_SPEC, Branch speculatively executed, procedure return

The counter counts procedure return instructions speculatively executed. Defined by the [BR_RETURN_RETIRED](#) event.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also [BR_RETURN_RETIRED](#).

0x007A, BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007C, ISB_SPEC, Barrier speculatively executed, ISB

The counter counts Instruction Synchronization Barrier instructions speculatively executed, including [CP15ISB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007D, DSB_SPEC, Barrier speculatively executed, DSB

The counter counts data synchronization barrier instructions speculatively executed, including [CP15DSB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007E, DMB_SPEC, Barrier speculatively executed, DMB

The counter counts data memory barrier instructions speculatively executed, including [CP15DSB](#). It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x0081, EXC_UNDEF, Exception taken, other synchronous

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only those exceptions *Taken locally* that are not counted as:

- Exception taken, Supervisor Call ([EXC_SVC](#)).
- Exception taken, Secure Monitor Call ([EXC_SMC](#)).
- Exception taken, Hypervisor Call ([EXC_HVC](#)).
- Exception taken, Instruction Abort ([EXC_PABORT](#)).
- Exception taken, Data Abort or SError ([EXC_DABORT](#)).
- Exception taken, IRQ ([EXC_IRQ](#)).
- Exception taken, FIQ ([EXC_FIQ](#)).

0x0082, EXC_SVC, Exception taken, Supervisor Call

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Supervisor Call exceptions that are *Taken locally*.

0x0083, EXC_PABORT, Exception taken, Instruction Abort

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Instruction Abort exceptions that are *Taken locally*.

0x0084, EXC_DABORT, Exception taken, Data Abort or SError

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions *Taken locally*.

0x0086, EXC_IRQ, Exception taken, IRQ

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only IRQ exceptions that are *Taken locally*, including Virtual IRQ exceptions.

0x0087, EXC_FIQ, Exception taken, FIQ

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only FIQ exceptions that are *Taken locally*, including Virtual FIQ exceptions.

0x0088, EXC_SMC, Exception taken, Secure Monitor Call

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

0x008A, EXC_HVC, Exception taken, Hypervisor Call

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions *Taken locally* in the hypervisor and those taken as an exception from Non-secure EL1.

0x008B, EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Instruction Abort exceptions not *Taken locally*.

0x008C, EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Data Abort or SError interrupt exceptions not *Taken locally*.

0x008D, EXC_TRAP_OTHER, Exception taken, other traps not Taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only those traps that are not counted as:

- Exception taken, Secure Monitor Call ([EXC_SMC](#)).
- Exception taken, Hypervisor Call ([EXC_HVC](#)).
- Exception taken, Instruction Abort not *Taken locally* ([EXC_TRAP_PABORT](#)).
- Exception taken, Data Abort or SError not *Taken locally* ([EXC_TRAP_DABORT](#)).
- Exception taken, IRQ not *Taken locally* ([EXC_TRAP_IRQ](#)).
- Exception taken, FIQ not *Taken locally* ([EXC_TRAP_FIQ](#)).

0x008E, EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only IRQ exceptions not *Taken locally*.

0x008F, EXC_TRAP_FIQ, Exception taken, FIQ not Taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only FIQ exceptions not *Taken locally*.

0x0090, RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire

The counter counts memory-read operations with acquire or acquirepc semantics that are speculatively executed.

0x0091, RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release

The counter counts memory-write operations with release semantics that are speculatively executed.

0x00A0, L3D_CACHE_RD, Attributable Level 3 data or unified cache access, read

This event is similar to Attributable Level 3 data or unified cache access, [L3D_CACHE](#), but the counter counts only attributable memory read operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A1, L3D_CACHE_WR, Attributable Level 3 data or unified cache access, write

This event is similar to Attributable Level 3 data or unified cache access, [L3D_CACHE](#), but the counter counts only attributable memory write operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A2, L3D_CACHE_REFILL_RD, Attributable Level 3 data or unified cache refill, read

This event is similar to Attributable Level 3 data or unified cache refill, [L3D_CACHE_REFILL](#), but the counter counts only attributable memory read operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3cache. See also [Relationship between REFILL events and associated access events](#). on page K3-7265

0x00A3, L3D_CACHE_REFILL_WR, Attributable Level 3 data or unified cache refill, write

This event is similar to Attributable Level 3 data or unified cache refill, [L3D_CACHE_REFILL](#), but the counter counts only attributable memory write operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3cache. See also [Relationship between REFILL events and associated access events](#). on page K3-7265

0x00A6, L3D_CACHE_WB_VICTIM, Attributable Level 3 data or unified cache Write-Back, victim

This event is similar to Attributable Level 3 data cache Write-Back, [L3D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If [ARMv8.4-PMU](#) is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If [ARMv8.4-PMU](#) is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

0x00A7, L3D_CACHE_WB_CLEAN, Level 3 data or unified cache Write-Back, cache clean

This event is similar to Attributable Level 3 data cache Write-Back, [L3D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

———— **Note** —————

The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x00A8, L3D_CACHE_INVAL, Attributable Level 3 data or unified cache access, invalidate

The counter counts each invalidation of a cache line in the Level 3 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If [ARMv8.4-PMU](#) is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If [ARMv8.4-PMU](#) is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

———— **Note** —————

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

K3.1.1 Relationship between REFILL events and associated access events.

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. [Table K3-2](#) shows this correspondence.

Table K3-2 Relationship between REFILL events and associated access events

REFILL event	Access event	Ratio REFILL/Access
0x0042 L1D_CACHE_REFILL_RD	0x0040 L1D_CACHE_RD	Attributable Level 1 cache refill rate, read
0x0043 L1D_CACHE_REFILL_WR	0x0041 L1D_CACHE_WR	Attributable Level 1 cache refill rate, write
0x004C L1D_TLB_REFILL_RD	0x004E L1D_TLB_RD	Attributable Level 1 TLB refill rate, read
0x004D L1D_TLB_REFILL_WR	0x004F L1D_TLB_WR	Attributable Level 1 TLB refill rate, write
0x0052 L2D_CACHE_REFILL_RD	0x0050 L2D_CACHE_RD	Attributable Level 2 data cache refill rate, read
0x0053 L2D_CACHE_REFILL_WR	0x0051 L2D_CACHE_WR	Attributable Level 2 data cache refill rate, write
0x005C L2D_TLB_REFILL_RD	0x005E L2D_TLB_RD	Attributable Level 2 data TLB refill rate, read

Table K3-2 Relationship between REFILL events and associated access events (continued)

REFILL event	Access event	Ratio REFILL/Access
0x005D L2D_TLB_REFILL_WR	0x005F L2D_TLB_WR	Attributable Level 2 data TLB refill rate, write
0x00A2 L3D_CACHE_REFILL_RD	0x00A0 L3D_CACHE_RD	Attributable Level 3 data cache refill rate, read
0x00A3 L3D_CACHE_REFILL_WR	0x00A1 L3D_CACHE_WR	Attributable Level 3 data cache refill rate, write

K3.2 Summary of events for exceptions taken to an Exception level using AArch64

Table K3-3 shows the events for exceptions taken to an Exception level using AArch64.

Table K3-3 Events for exceptions taken to an Exception level using AArch64

ESR.EC	Description	Event number and classification for exceptions		
		<i>Taken locally</i>	<i>Not Taken locally</i>	
0x00	Unknown or uncategorized	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER

-	FIQ interrupt	0x0087, EXC_FIQ	0x008F, EXC_TRAP_FIQ
-	All other values	-	0x008D, EXC_TRAP_OTHER

- a. The exception reported with EC 0x1F is IMPLEMENTATION DEFINED, and therefore it is IMPLEMENTATION DEFINED which event counts the exception, except that the event that counts the exception must correctly indicate whether the exception was *Taken locally*.

Note

The [Glossary](#) defines the term *Taken locally*, that is used in event definitions in this chapter. See also [Exception levels on page D1-2146](#) for more information.

Appendix K4

Recommendations for reporting memory attributes on an interconnect

This appendix describes the ARM recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- [ARM recommendations for reporting memory attributes on an interconnect on page K4-7270.](#)

K4.1 ARM recommendations for reporting memory attributes on an interconnect

The ARM architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that ARM strongly recommends, but these recommendations do not form part of the ARMv8 architecture.

K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the ARM architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, ARM strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when memory accesses are forced to be Non-cacheable

ARM also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in [Enabling and disabling the caching of memory accesses on page D4-2357](#) for AArch64 and in [Enabling and disabling the caching of memory accesses in AArch32 state on page G4-5429](#) for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.

Appendix K5

Additional Information for Implementations of the Generic Timer

This appendix gives additional information about implementations of the Generic Timer. It contains the following sections:

- *Providing a complete set of features in a system level implementation on page K5-7272.*
- *Gray-count scheme for timer distribution scheme on page K5-7274.*

K5.1 Providing a complete set of features in a system level implementation

As an example system design, using memory-mapped Generic Timer components as described in [Chapter I2 System Level Implementation of the Generic Timer](#), the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A **CNTCTLBase** control frame.
- The following **CNTBaseN** timer frames:
 - Frame 0** Accessible by Non-secure accesses, with second view and virtual capability. This provides the Non-secure EL1&0 timers.
 - Frame 1** Accessible by Non-secure accesses, with no second view and no virtual capability. This provides the Non-secure EL2 timers.
 - Frame 2** Accessible only by Secure accesses, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
 - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
 - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.
 - Frame 3** Accessible only by Secure accesses, with no second view and no virtual capability. This provides the Secure EL3 timers.

———— **Note** —————

This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and accessibility as memory pages in the different translation regimes, is as follows:

CNTCTLBase

The control frame. This frame is accessible in both the Secure and Non-secure memory maps, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase0

The first view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTELOBase0

The second view of **CNTBase0**, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

CNTBase1

The first and only view of the Non-secure EL2 timers. This frame is accessible only in Non-secure memory map, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase2 The first view of the Secure EL1&0, or PL1&0 timers.

———— **Note** —————

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see [Security state, Exception levels, and AArch32 execution privilege](#) on page G1-5218.

—————

This frame is accessible only in the Secure memory map, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of **CNTBase2**, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

———— **Note** —————

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

—————

This frame is accessible only in the Secure memory map, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTBase3 The first and only view of the EL3 timers. This frame is accessible only in the Secure memory map, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is not accessible.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, this frame is not accessible.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

———— **Note** —————

[About the Virtual Memory System Architecture \(VMSA\)](#) on page D5-2384 describes the VMSAv8-64 translation regimes, and [About VMSAv8-32](#) on page G5-5456 describes the VMSAv8-32 translation regimes.

K5.2 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

```
Gray[N] = Count[N]
Gray[i] = (XOR(Gray[N:i+1])) XOR Count[i] for N-1 >= i >= 0
Count[i] = XOR(Gray[N:i]) for N >= i >= 0
```

This is for an N+1 bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

———— **Note** —————

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be 2^n , where n is an integer. A switch-over can occur only on the $2n+1$ boundary to avoid losing the Gray-coding property on a switch-over.

Appendix K6

Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the ARM instruction sets, and their *Unified Assembler Language* (UAL) equivalents. It contains the following section:

- [Legacy Instruction Syntax on page K6-7276](#).

K6.1 Legacy Instruction Syntax

Early versions of the ARM Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K6.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K6-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

K6.1.3 FCONST

The syntax of FCONST is

FCONST<dest>{<c>} <Fd>, #<imm8>

where:

- <dest> Specifies the destination data type. It must be one of:
- S Single-precision floating-point.
 - D Double-precision floating-point.
- <c> This is an optional field. It specifies the condition under which the instruction is executed. See [Conditional execution on page F2-3655](#) for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).
- <Fd> Specifies the destination register. It must be one of:
- <Dd> 64-bit name of the SIMD&FP destination register.
 - <Sd> 32-bit name of the SMID&FP destination register.
- <imm8> Specifies the immediate value used to generate the floating-point constant.
- FCONSTD{<c>} <Dd>, #<imm8> maps to VMOV.F64 <Dd>, #<fpimm>
- FCONSTS{<c>} <Sd>, #<imm8> maps to VMOV.F32 <Sd>, #<fpimm>

Appendix K7

Address translation examples

This appendix gives examples of address translations using the translation regimes described in [Chapter D5 *The AArch64 Virtual Memory System Architecture*](#) and [Chapter G5 *The AArch32 Virtual Memory System Architecture*](#). It contains the following sections:

- [AArch64 Address translation examples](#) on page K7-7284.
- [AArch32 Address translation examples](#) on page K7-7296.

———— **Note** —————

This chapter gives examples of translation table lookups for the ARMv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in [Chapter D5 *The AArch64 Virtual Memory System Architecture*](#) or [Chapter G5 *The AArch32 Virtual Memory System Architecture*](#) then the information in [Chapter D5](#) or [Chapter G5](#) must be taken as the definition of the required behavior.

K7.1 AArch64 Address translation examples

Figure D5-1 on page D5-2393 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. *The VMSAv8-64 address translation system on page D5-2392* describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D5-2399 specifies the relevant registers, including the TCR_ELx and TTBR_ELx, or TTBR_ELxs, for each stage of address translation.

For any stage of translation, a TCR_ELx.TnSZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is $2^{(64-TnSZ)}$.

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
 - At the highest lookup level used for the appropriate translation granule size.
 - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

- The IA size is smaller than the largest size for the translation level, see *Reduced IA width on page D5-2410*.
- For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see *Concatenated translation tables on page D5-2411*.

For examples of performing the initial lookup, see *Examples of performing the initial lookup*.

- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see *Full translation flows for VMSAv8-64 address translation on page K7-7290*.

K7.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- *Performing the initial lookup using the 4KB translation granule*.
- *Performing the initial lookup using the 16KB granule on page K7-7286*.
- *Performing the initial lookup using the 64KB translation granule on page K7-7288*.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that [Table D5-12 on page D5-2417](#) shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system on page D5-2392*.

Note

For stage 2 translations, the same principles apply to an initial lookup that [Table D5-12 on page D5-2417](#) shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 4KB translation granule on page K7-7285*.
- *Initial lookup at level 1, 4KB translation granule on page K7-7285*.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 4KB granule on page D5-2417*.

Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$. As Table D5-12 on page D5-2417 shows, a stage 1 or stage 2 initial lookup at level 0 is required when $39 \leq n \leq 47$. For these lookups:

- $TTBR_ELx[47:(n-35)]$ specify the translation table base address.
- Bits $[n:39]$ of the input address are bits $[(n-36):3]$ of the descriptor offset in the translation table.

———— **Note** ————

This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the $TTBR_ELx$ are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- $TTBR_ELx$ bits $[47:10]$ specify the translation table base address.
- Input address bits $[45:39]$ specify bits $[9:3]$ of the descriptor offset.

Figure K7-1 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 12$, $y = x + 35$. When y is 47 the field marked ‡ is absent.

‡ For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-1 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0

Initial lookup at level 1, 4KB translation granule

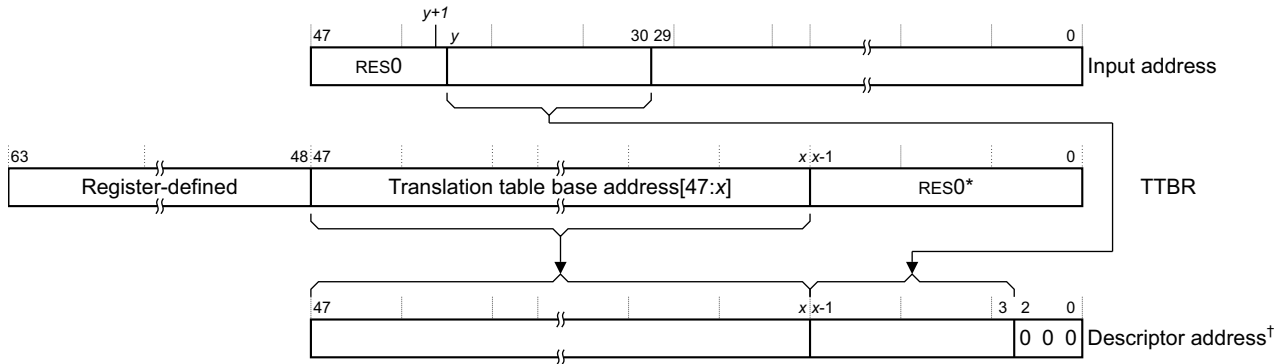

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$.

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-12 on page D5-2417 shows, this applies to $IA[n:0]$, where $30 \leq n \leq 38$. For these lookups:

- There is a single translation table at this level.
- $TTBR_ELx[47:(n-26)]$ specify the translation table base address.
- Bits $[n:30]$ of the input address are bits $[(n-27):3]$ of the descriptor offset in the translation table.

Figure K7-2 on page K7-7286 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 12$, $y = x + 26$.

[†] For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-12 on page D5-2417 shows, this applies to $IA[n:0]$, where $39 \leq n \leq 42$. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)} \times 4\text{KB}$. This means $TTBR_ELx[(n-27):12]$ must be zero.
- $TTBR_ELx[47:(n-26)]$ specify the base address of the block of concatenated translation tables.
- Bits $[n:30]$ of the input address are bits $[(n-27):3]$ of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-3 shows this lookup.

Supported input address range is $IPA[y:0]$, $4 \leq x \leq 16$, $y = x + 26$. The field marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D5-14 on page D5-2420 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D5-2392.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-14 on page D5-2420 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 16KB translation granule.*
- *Initial lookup at level 1, 16KB translation granule.*

In all cases, for a stage 2 translation, the `VTCR_EL2.SL0` field must indicate the required initial lookup level, and this level must be consistent with the value of the `VTCR_EL2.T0SZ` field, see *Overview of stage 2 translations, 16KB granule* on page D5-2420.

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is `IA[n:0]`. As Table D5-13 on page D5-2419 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, `IA[47:0]`. For this lookup:

- The required translation table has only two entries, meaning its size is 16 bytes, and it must be aligned to 16 bytes.
- `TTBR_ELx[47:4]` specify the translation table base address.
- Bit[47] of the input address is bits[3] of the descriptor offset in the translation table.

Figure K7-4 shows this lookup.

Supported input address range is `IA[47:0]`. The field marked ‡ is `RES0*`.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default `RES0` definition, see the register description for more information.

Figure K7-4 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0

Initial lookup at level 1, 16KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is `IA[n:0]`.

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-14 on page D5-2420 shows, this applies to `IA[n:0]`, where $36 \leq n \leq 46$. For these lookups:

- There is a single translation table at this level.
- `TTBR_ELx[47:(n-32)]` specify the translation table base address.
- Bits[$n:36$] of the input address are bits[$(n-33):3$] of the descriptor offset in the translation table.

Figure K7-5 on page K7-7288 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 14$, $y = x + 32$.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-5 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-14 on page D5-2420 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, $IA[47:0]$. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2 \times 16\text{KB}$. This means $TTBR_ELx[14]$ must be zero.
- $TTBR_ELx[47:15]$ specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-6 shows this lookup.

Supported input address range is $IPA[47:0]$. The bit marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D5-16 on page D5-2424 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D5-2392.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-16 on page D5-2424 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 1, 64KB translation granule.*
- *Initial lookup at level 2, 64KB translation granule.*

In all cases, for a stage 2 translation, the `VTCR_EL2.SL0` field must indicate the required initial lookup level, and this level must be consistent with the value of the `VTCR_EL2.T0SZ` field, see *Overview of stage 2 translations, 64KB granule on page D5-2424.*

Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$. As Table D5-16 on page D5-2424 shows, a stage 1 or stage 2 initial lookup at level 1 is required when $42 \leq n \leq 47$. For these lookups:

- The size of the translation table is $2^{(n-39)}$ bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits $[n:42]$ of the input address are bits $[(n-39):3]$ of the descriptor offset in the translation table.
- Bits $[47:(n-38)]$ of the `TTBR_ELx` specify the translation table base address.

Figure K7-7 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 9$, $y = x + 38$. When y is 47 the field marked ‡ is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-7 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1

Initial lookup at level 2, 64KB translation granule

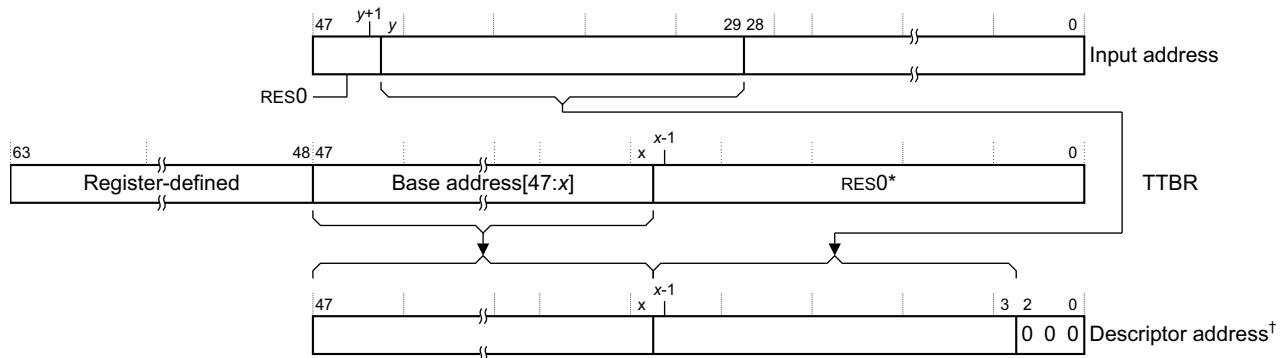

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$.

For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D5-16 on page D5-2424 shows, this applies to $IA[n:0]$, where $29 \leq n \leq 41$. For these lookups:

- There is a single translation table at this level.
- `TTBR_ELx[47:(n-25)]` of the specify the translation table base address.
- Bits $[n:29]$ of the input address are bits $[(n-26):3]$ of the descriptor offset in the translation table.

Figure K7-8 on page K7-7290 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 16$, $y = x + 25$.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

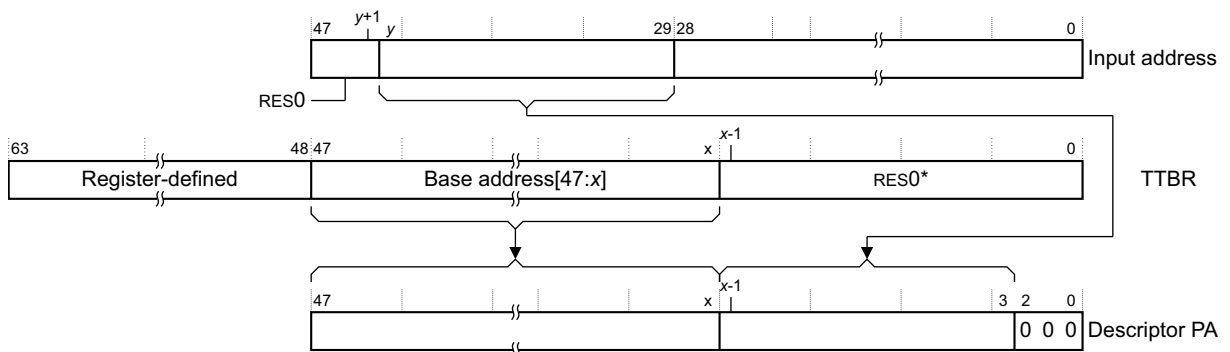

Figure K7-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D5-16 on page D5-2424 shows, this applies to $IA[n:0]$, where $42 \leq n \leq 45$. For these lookups:

- There are $2^{(m-41)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(m-41)} \times 64\text{KB}$. This means $TTBR_ELx[(n-26):16]$ must be zero.
- $TTBR_ELx[47:(n-25)]$ specify the base address of the block of translation tables.
- Bits $[n:42]$ of the input address are bits $[(n-26):16]$ of the descriptor offset from the base address of the block of translation tables.

Figure K7-9 shows this lookup.

Supported input address range is $IPA[y:0]$, $4 \leq x \leq 20$, $y = x + 25$.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

K7.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate $TTBR_ELx$. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.

- Do not have any concatenation of translation tables.
- Cover only the 4KB and the 64KB translation granules.

[Examples of performing the initial lookup on page K7-7284](#) described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note

Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- [The address and properties fields shown in the translation flows.](#)
- [Full translation flow using the 4KB granule and starting at level 0.](#)
- [Full translation flow using the 4KB granule and starting at level 1 on page K7-7293.](#)
- [Full translation flow using the 64KB granule and starting at level 1 on page K7-7294.](#)
- [Full translation flow using the 64KB granule and starting at level 2 on page K7-7295.](#)

The address and properties fields shown in the translation flows

For the Non-secure EL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

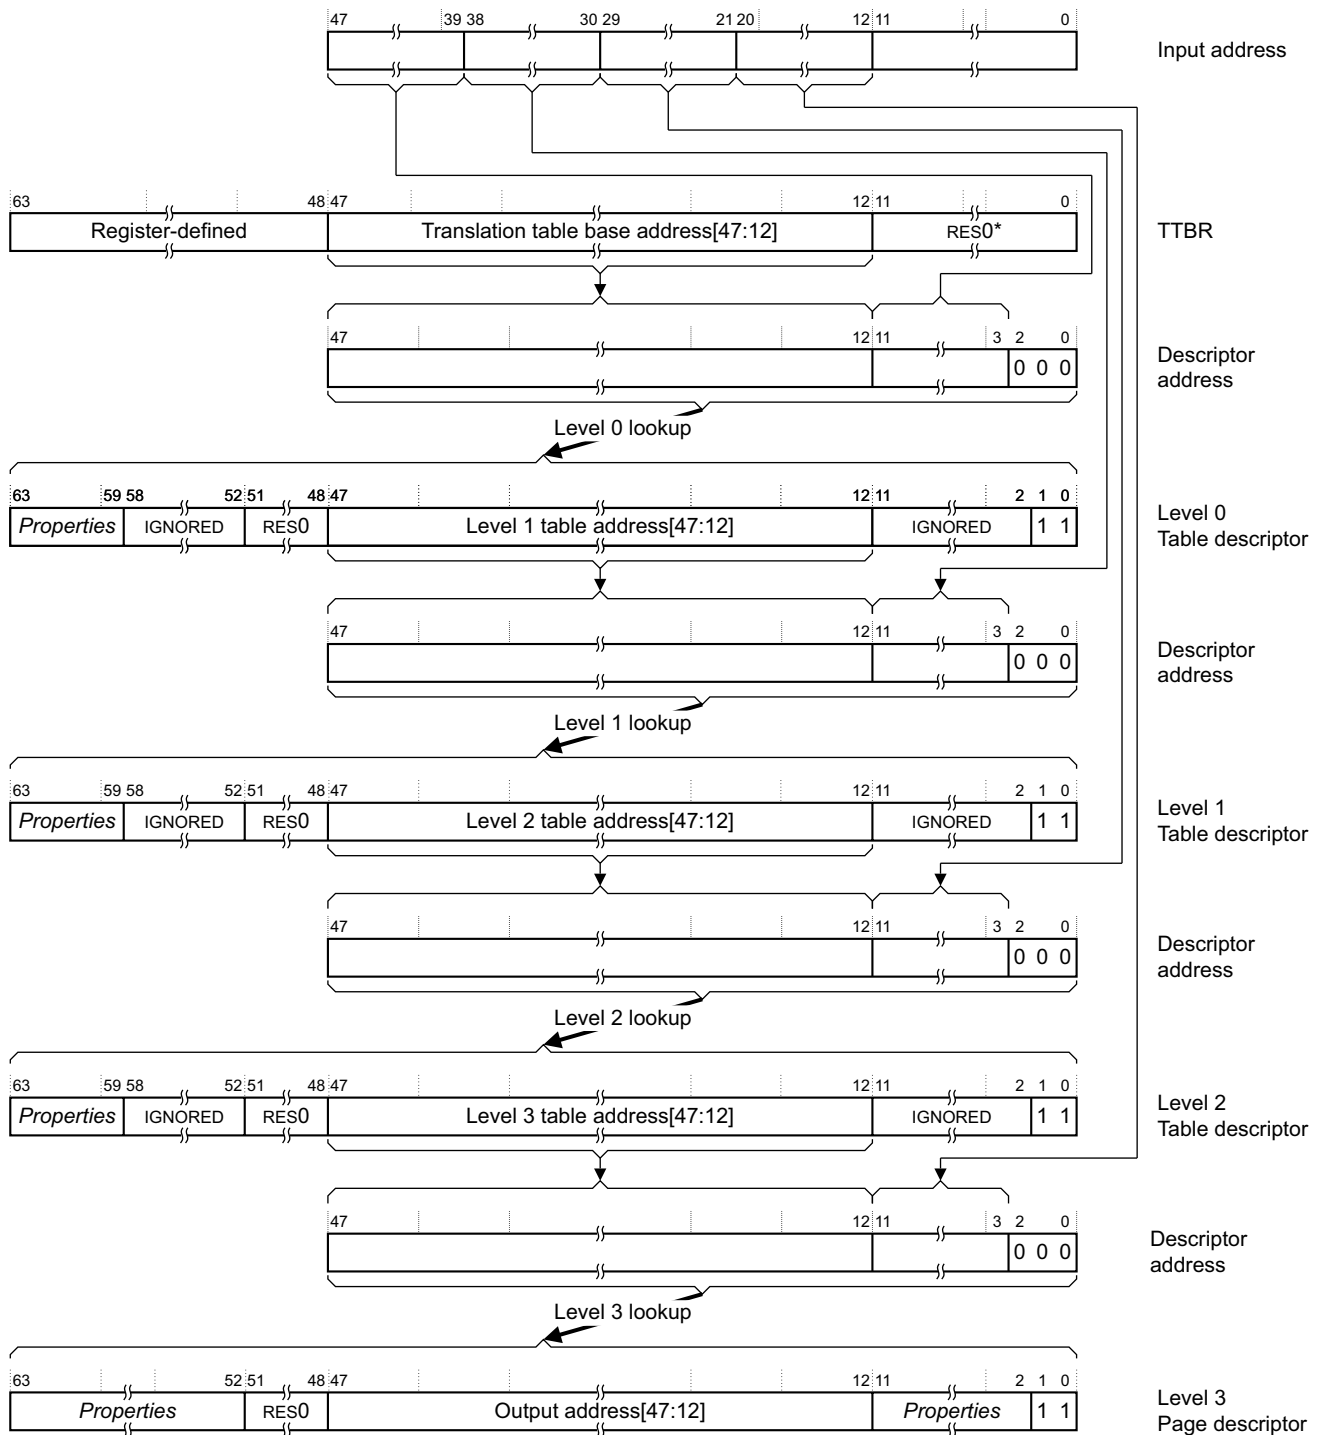

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2449](#).

Full translation flow using the 4KB granule and starting at level 0

[Figure K7-10 on page K7-7292](#) shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see [The address and properties fields shown in the translation flows](#).

For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

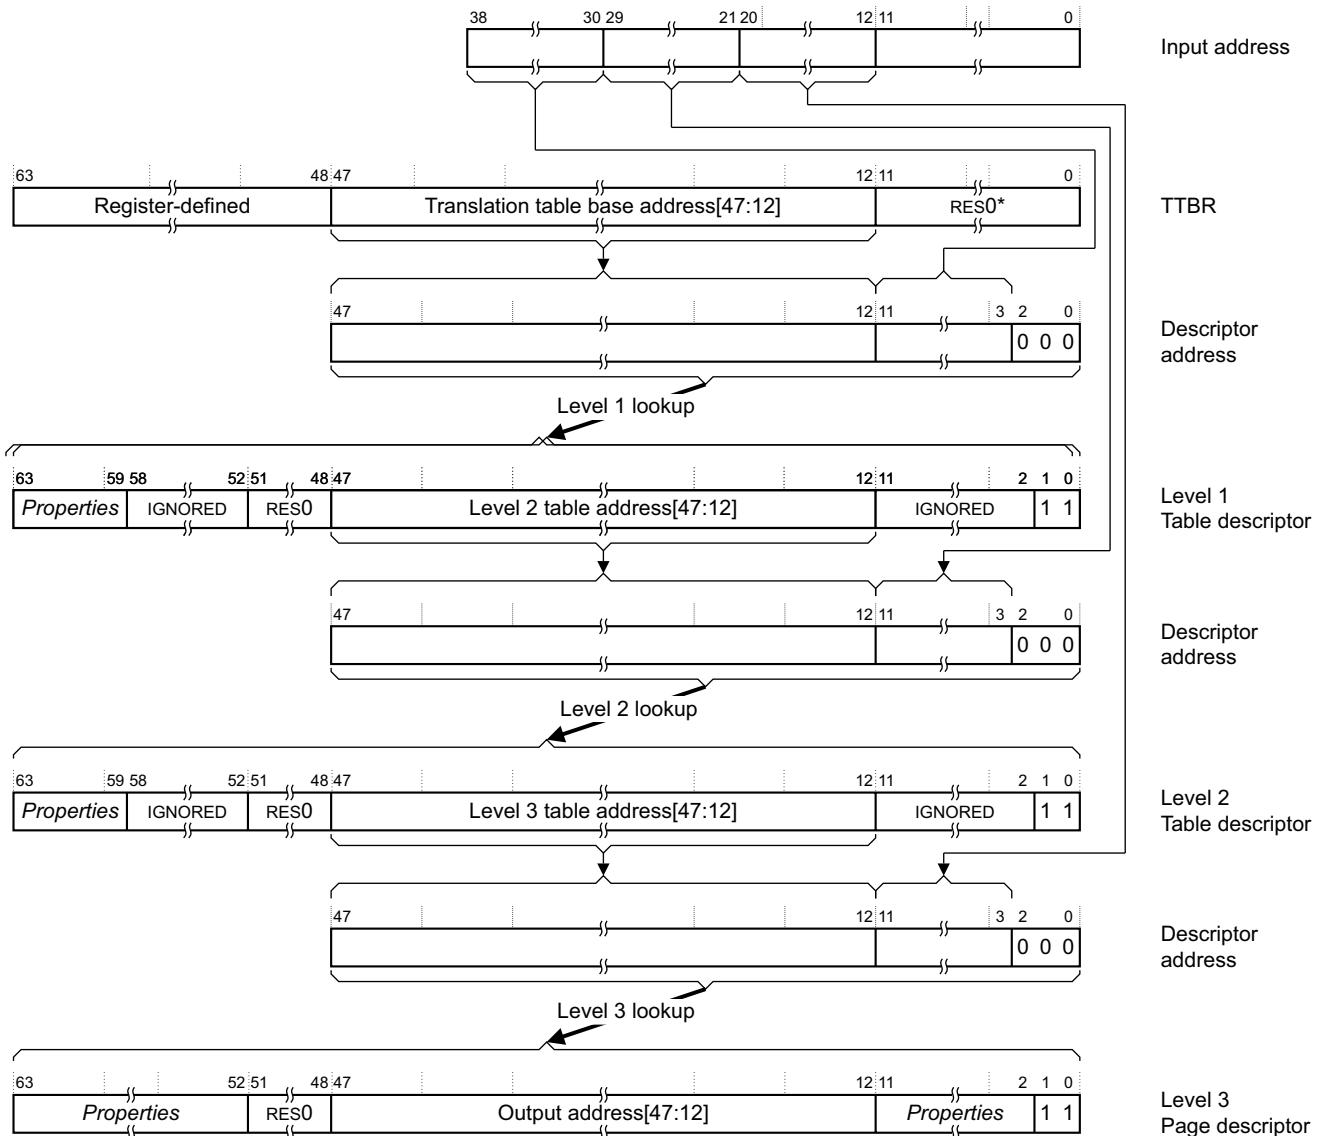

Figure K7-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule

If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-10 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Full translation flow using the 4KB granule and starting at level 1

Figure K7-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-7291.

For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-11 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-10 on page K7-7292, shows how the translation for the 42-bit address start the same lookup process one stage later.

Full translation flow using the 64KB granule and starting at level 1

Figure K7-10 on page K7-7292 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-7291.

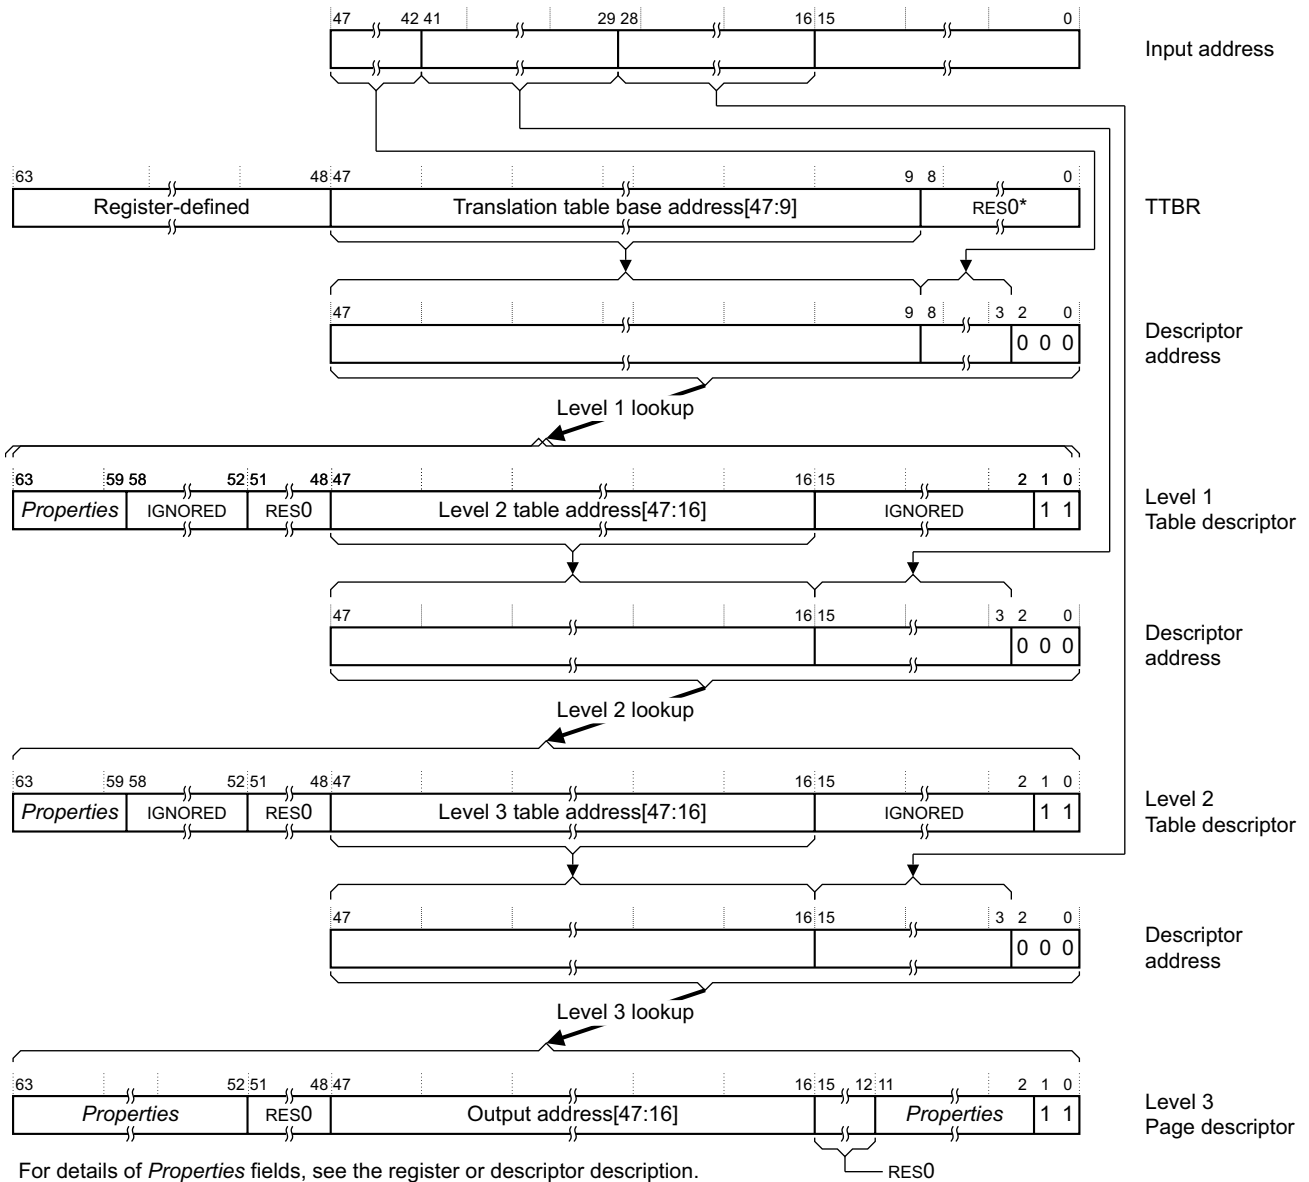

Figure K7-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule* on page K7-7288, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the `TTBR_ELx` is extended, at the low-order end, to be bits[47:9].

Full translation flow using the 64KB granule and starting at level 2

Figure K7-11 on page K7-7293 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-7291.

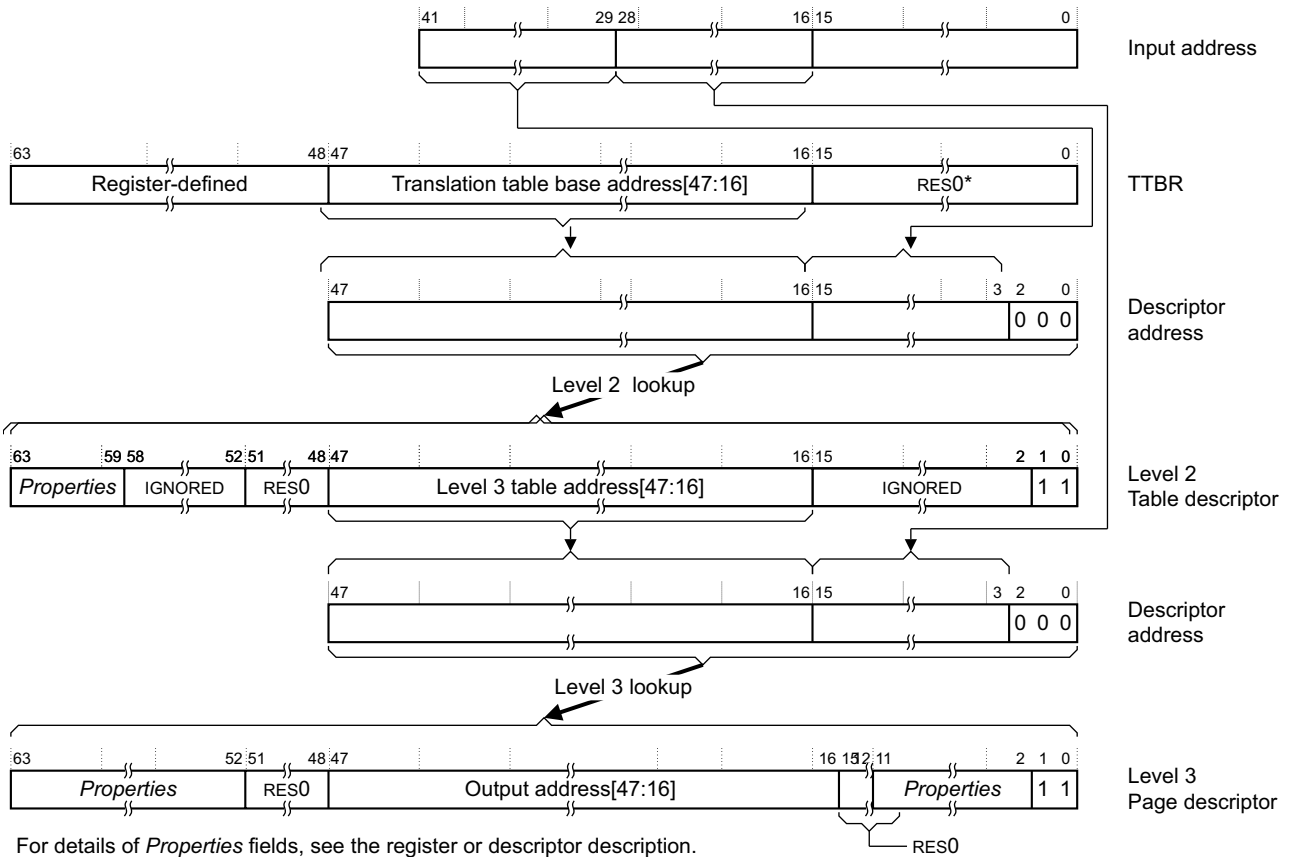

Figure K7-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits [63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-12 on page K7-7294, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
 - The translation table size for this level is 64KB.
 - The required translation table alignment for this level is 64KB.
 - The Base address field in the `TTBR_ELx` is bits [47:16].

K7.2 AArch32 Address translation examples

The following sections give address translation examples for the VMSSAv8-32 address translation formats:

- [Address translation examples using the VMSSAv8-32 Short descriptor translation table format.](#)
- [Address translation examples using the VMSSAv8-32 Long descriptor translation table format on page K7-7301.](#)

K7.2.1 Address translation examples using the VMSSAv8-32 Short descriptor translation table format

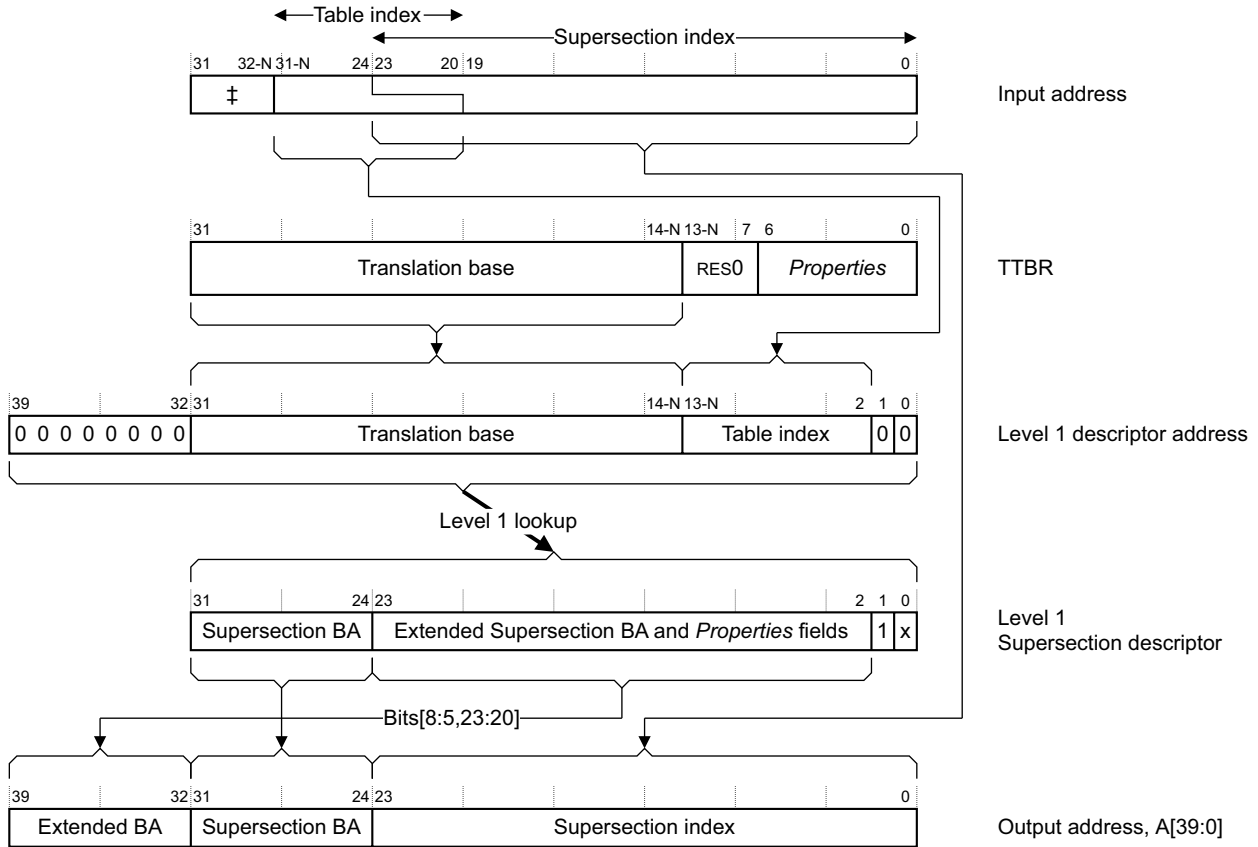

[VMSSAv8-32 Short-descriptor translation table format descriptors on page G5-5474](#) describes the memory section and page option for a single VMSSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- [Translation flow for a Supersection.](#)
- [Translation flow for a Section on page K7-7297.](#)
- [Translation flow for a Large page on page K7-7298.](#)
- [Translation flow for a Small page on page K7-7300.](#)

[The address and Properties fields shown in the translation flows on page K7-7300](#) summarizes the information returned by the lookup.

Translation flow for a Supersection

[Figure K7-14 on page K7-7297](#) shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see [The address and Properties fields shown in the translation flows on page K7-7300](#).

‡ This field is absent if N is 0
 BA = Base address
 For a translation based on TTBR0, N is the value of TTBCR.N
 For a translation based on TTBR1, N is 0
 For details of *Properties* fields, see the register or descriptor description

Figure K7-14 VMSAv8-32 Short-descriptor Supersection address translation

Note

Figure K7-14 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the *Supersection index* bits of the address overlap the bottom four bits of the *Table index* bits. For more information, see [Additional requirements for Short-descriptor format translation tables on page G5-5477](#).

Translation flow for a Section

Figure K7-15 on page K7-7298 shows the complete translation flow for a Section. For more information about the fields shown in this figure see [The address and Properties fields shown in the translation flows on page K7-7300](#).

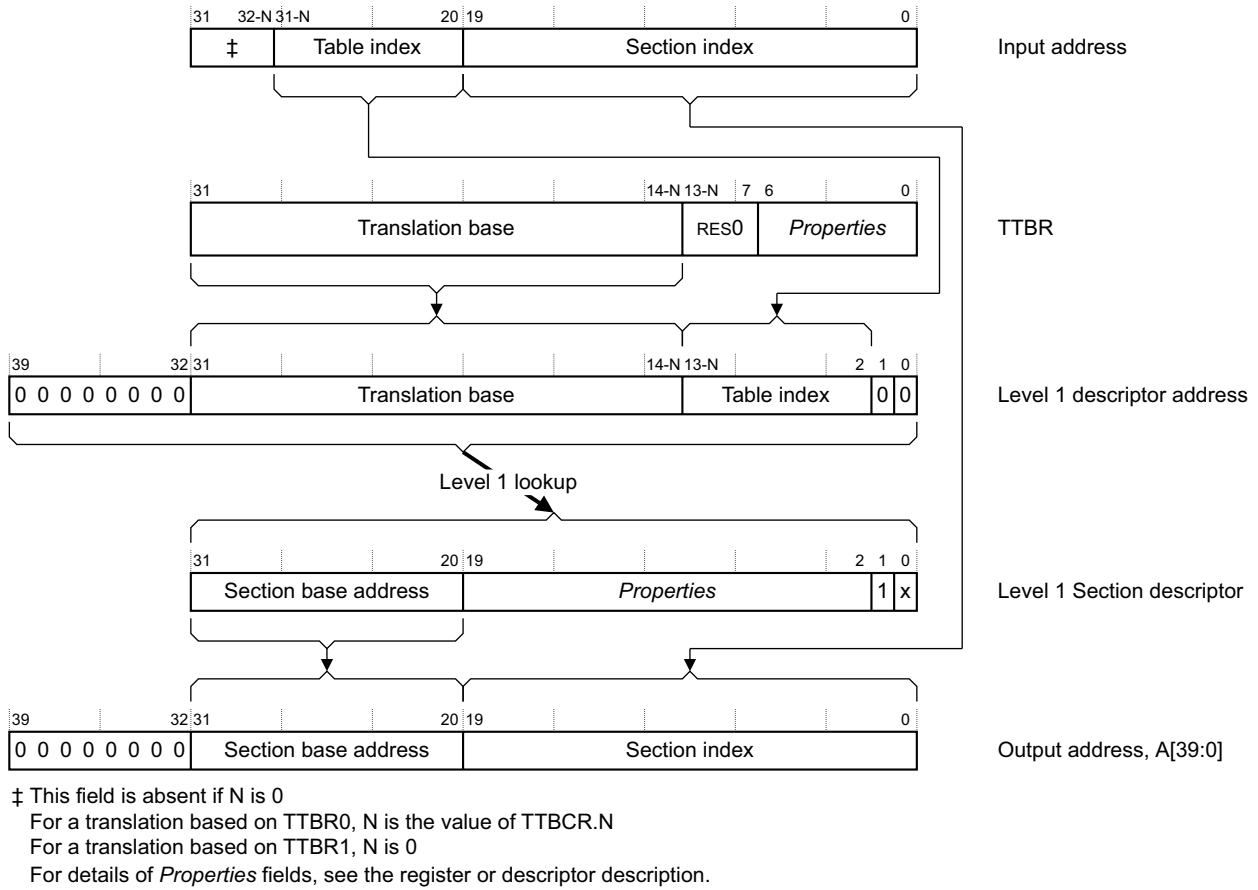

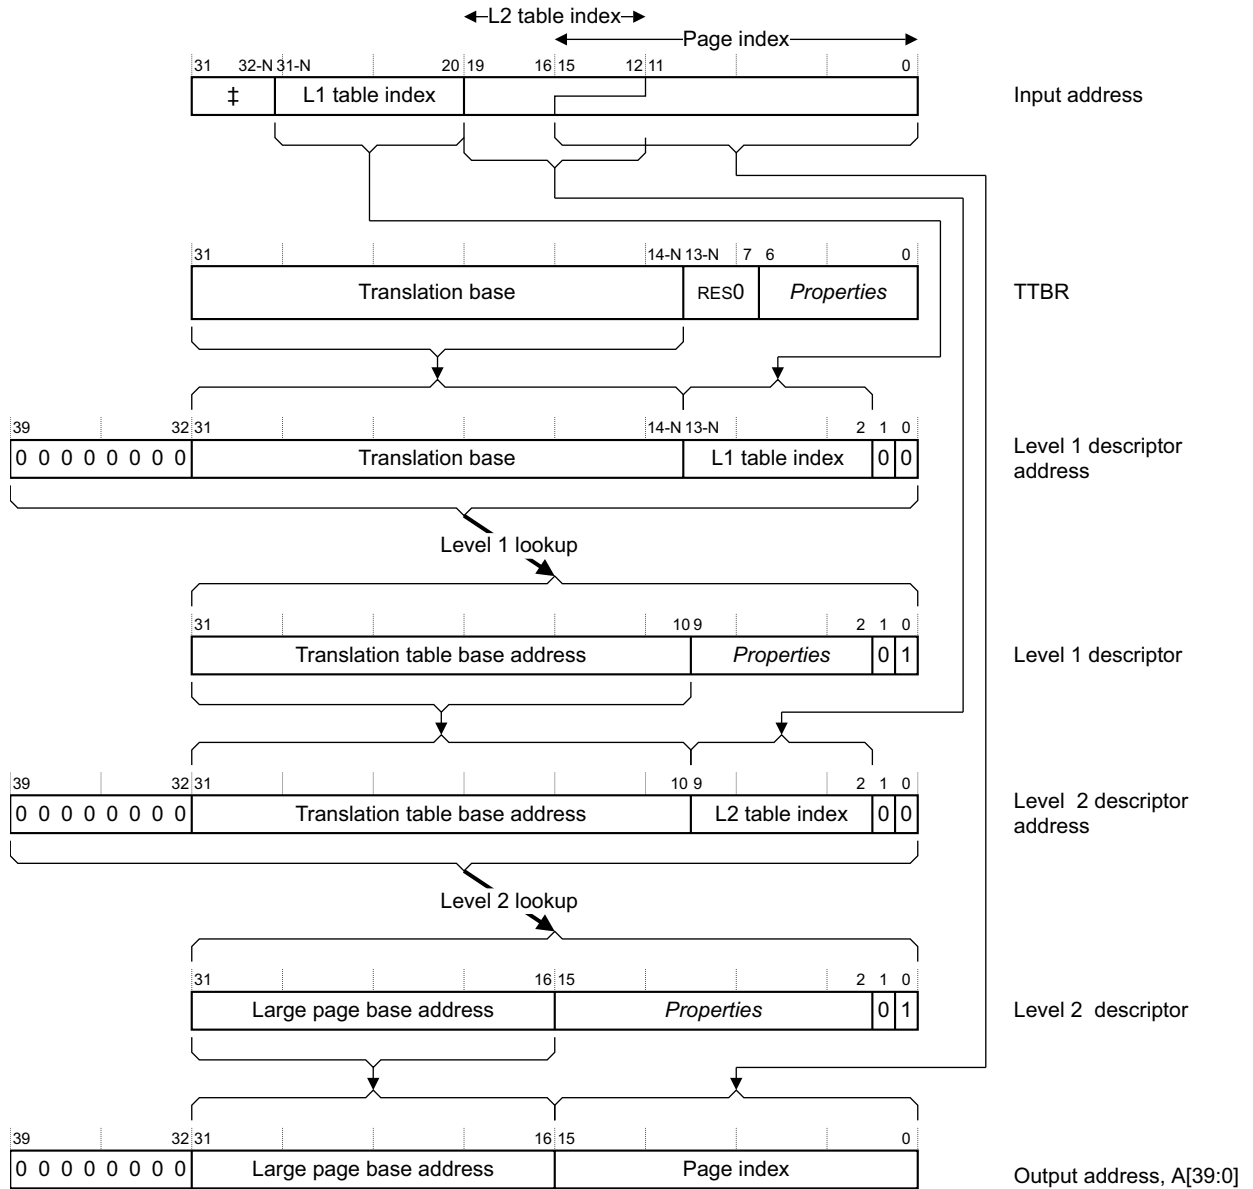

Figure K7-15 VMSAv8-32 Short-descriptor Section address translation

Translation flow for a Large page

Figure K7-16 on page K7-7299 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K7-7300*.

\ddagger This field is absent if N is 0
L1 = Level 1, L2 = Level 2
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description

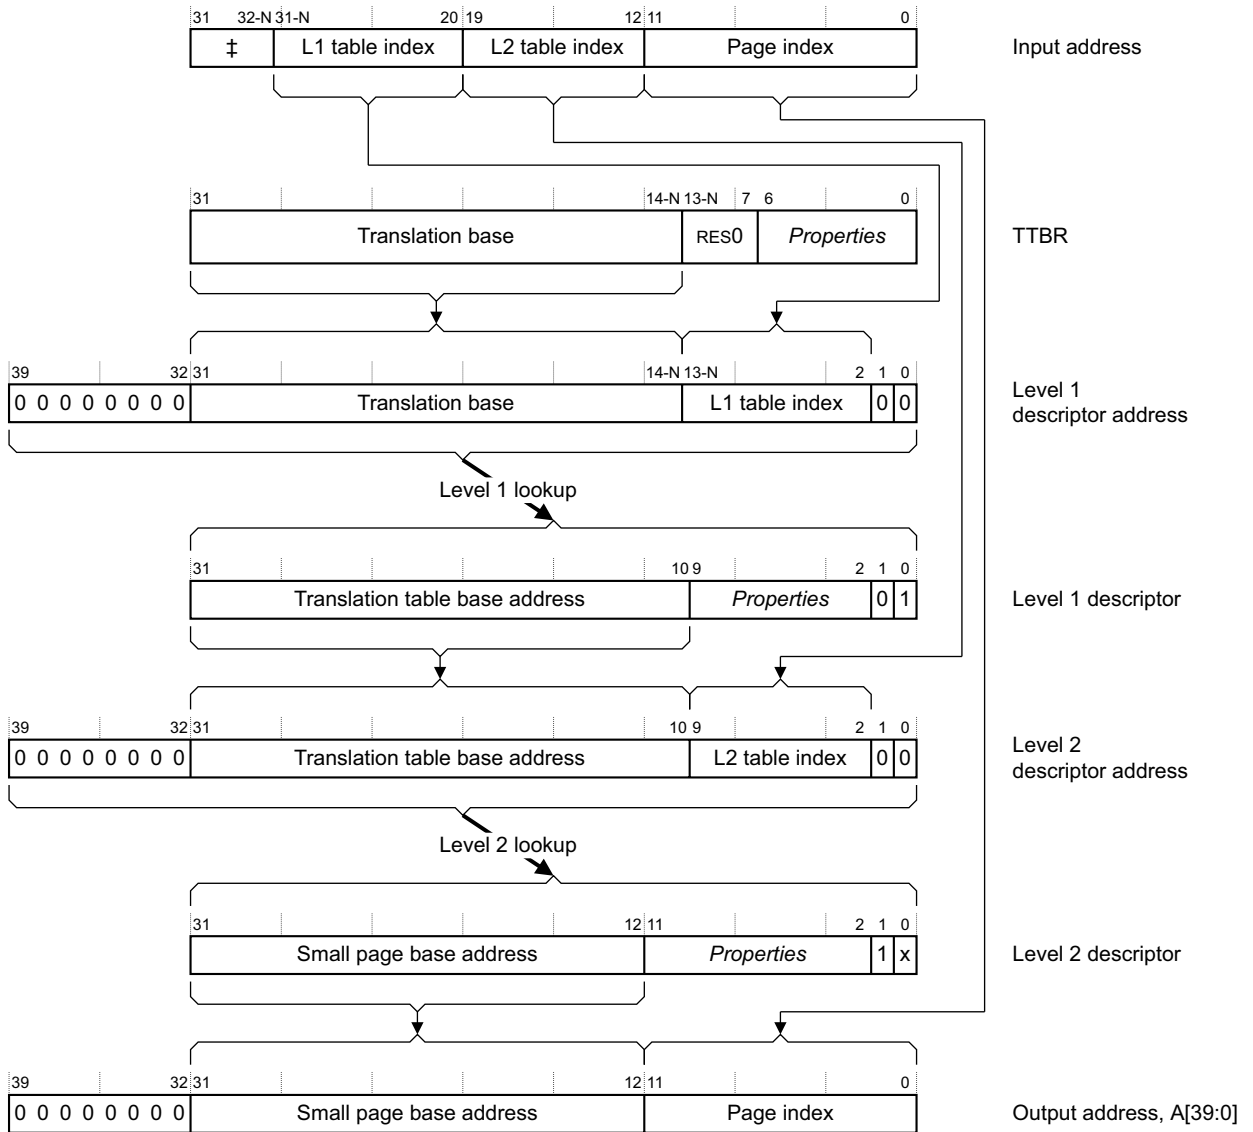

Figure K7-16 VMSAv8-32 Short-descriptor Large page address translation

Note

Figure K7-16 shows how, when the input address, the VA, addresses a Large page, the top four bits of the *page index* bits of the address overlap the bottom four bits of the *level 1 table index* bits. For more information, see [Additional requirements for Short-descriptor format translation tables on page G5-5477](#).

Translation flow for a Small page

Figure K7-17 on page K7-7300 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K7-7300.*

‡ This field is absent if N is 0
 L1 = Level 1, L2 = Level 2
 For a translation based on TTBR0, N is the value of TTBCR.N
 For a translation based on TTBR1, N is 0
 For details of *Properties* fields, see the register or descriptor description.

Figure K7-17 VMSAv8-32 Short-descriptor Small page address translation

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G5-5469, and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor translation table format descriptors* on page G5-5474 describes the descriptors formats.

K7.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format

As described in *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G5-5497, in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

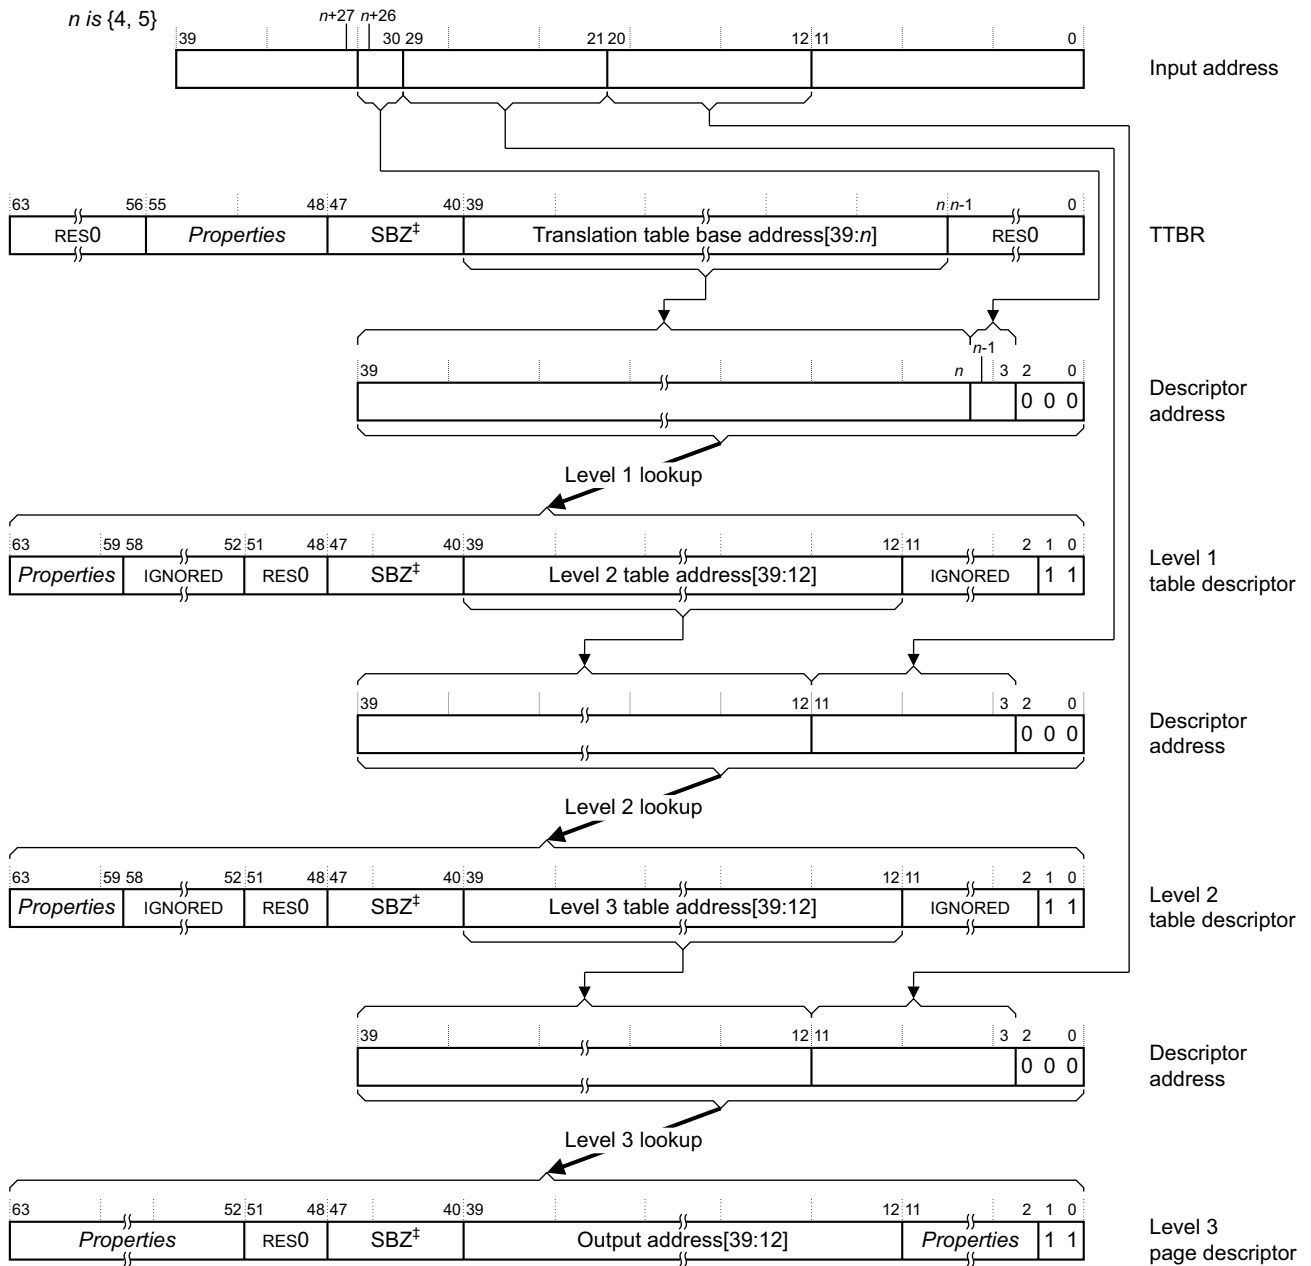

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

- *Full translation flow, starting at level 1 lookup.*
- *Full translation flow, starting at level 2 lookup* on page K7-7303.

The address and Properties fields shown in the translation flows on page K7-7300 summarizes the information returned by the lookup.

Full translation flow, starting at level 1 lookup

Figure K7-18 on page K7-7302 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-7300.

For details of *Properties* fields, see the register or descriptor description.

‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

Figure K7-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

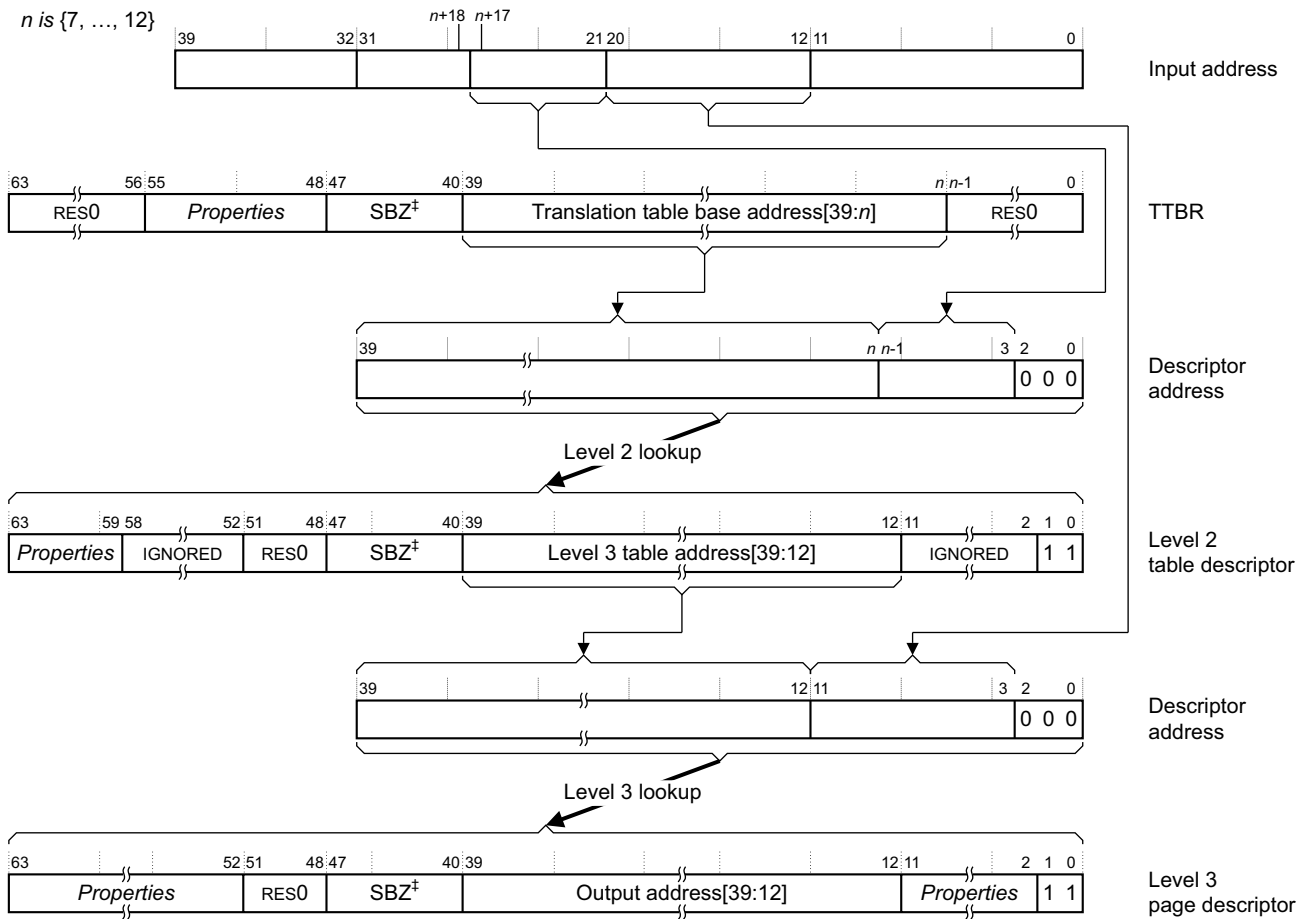

If bits[47:40] of the **TTBR** or the descriptor are not zero then the lookup will generate an Address size fault, see [Address size fault on page G5-5548](#).

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in [Figure K7-18](#) only as follows:

- The possible values of *n* are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

Full translation flow, starting at level 2 lookup

Figure K7-19 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-7300.

For details of *Properties* fields, see the register or descriptor description.

‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

Figure K7-19 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 2

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see *Address size fault* on page G5-5548.

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in Figure K7-19 only as follows:

- The possible values of n are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup on page G5-5469](#), and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, [VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5483](#) describes the descriptors formats.

Appendix K8

Example OS Save and Restore Sequences

This appendix provides possible OS Save and Restore sequences for a v8 Debug implementation. It contains the following sections:

- [Save Debug registers on page K8-7306.](#)
- [Restore Debug registers on page K8-7308.](#)

K8.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.
; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters

```
; (1) Set OS lock.
MOV    X2,#1                ; Set the OS lock. In AArch64 state, the OS lock
MSR    OSLAR_EL1,X2        ; is writable via OSLAR.
ISB                               ; Context synchronization event
```

```
; (2) Walk through the registers, saving them
MRS    X1,OSDTRRX_EL1      ; Read DTRRX
MRS    X2,OSDTRTX_EL1      ; Read DTRTX
STP    W1,W2,[X0],#8        ; Save { DTRRX, DTRTX }
MRS    X1,OSECCR_EL1        ; Read ECCR
MRS    X2,MDSCR_EL1        ; Read DSCR
STP    W1,W2,[X0],#8        ; Save { ECCR, DSCR }
[ AARCH32_SUPPORTED
MRS    X1,DBGVCR32_EL2      ; Read DBGVCR
MRS    X2,DBGCLAIMCLR_EL1   ; Read CLAIM - note, have to read via CLAIMCLR
STP    W1,W2,[X0],#8        ; Save { VCR, CLAIM }
]
```

```
; Macros for saving off a "register pair"
;; $WB      is W for watchpoint, B for breakpoint
;; $num     is the pair's number
;; X0 contains a pointer for the value words
;; X1 contains a pointer for the control words
;; W2 contains the max index
MACRO
SaveRP $WB,$num, $exit
MRS    X3,DBG$WB.VR$num._EL1 ; Read DBGxVRn
STR    X3,[X0],#8            ; Save { xVRn }
MRS    X3,DBG$WB.CR$num._EL1 ; Read DBGxCRn
STR    W3,[X0],#4            ; Save { xCRn }.
[ $num > 1 :LAND: $num < 15
CMP    W1,#$num
BEQ    $exit
]
MEND
```

```
; (3) Breakpoints
MRS    X1,ID_AA64DFR0_EL1
UBFX   W1,W1,#12,#4          ; Extract BRPs field

    MSR    OSLAR_EL1,X2             ; is writable via OSLAR.

    ; (6) A final ISB guarantees the restored register values are visible to subsequent
    ; instructions.
    ISB

    ; (7) Return the pointer to first word not read. This pointer is already in X0, so
    ; all that is needed is to return from this function.
    RET
```

Appendix K9

Recommended Upload and Download Processes for External Debug

This appendix contains the following section:

- [Using memory access mode in AArch64 state on page K9-7312.](#)

———— **Note** —————

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

—————

K9.1 Using memory access mode in AArch64 state

Figure K9-1 and Figure K9-2 on page K9-7313 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer n words of data:

- The download sequence needs $n+6$ accesses by the external debug interface.
- The upload sequence needs $n+8$ accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling `EDSCR` after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the `EDSCR.ERR` flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the `EDSCR.ERR` flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in `X0`. `EDSCR.ERR` might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

———— **Note** ————

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

Figure K9-1 Fast code download in AArch64 state (external host to target)

In Figure K9-1 on page K9-7312, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
 - a. Write address [31:0] to `DBGDTRRX_EL0`.
 - b. Write address [63:32] to `DBGDTRTX_EL0`.
 - c. Write MRS `X0, DBGDTR_EL0` to `EDITR`. The PE executes this instruction.
 - d. Set `EDSCR.MA` to 1.
2. Loop n times. From the external debug interface:
 - a. Write to `DBGDTRRX_EL0`. The PE reads the word from `DTRRX` and stores it to memory. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
 - a. Clear `EDSCR.MA` to 0.
 - b. Read `EDSCR` to check for overruns or Data Aborts during download.

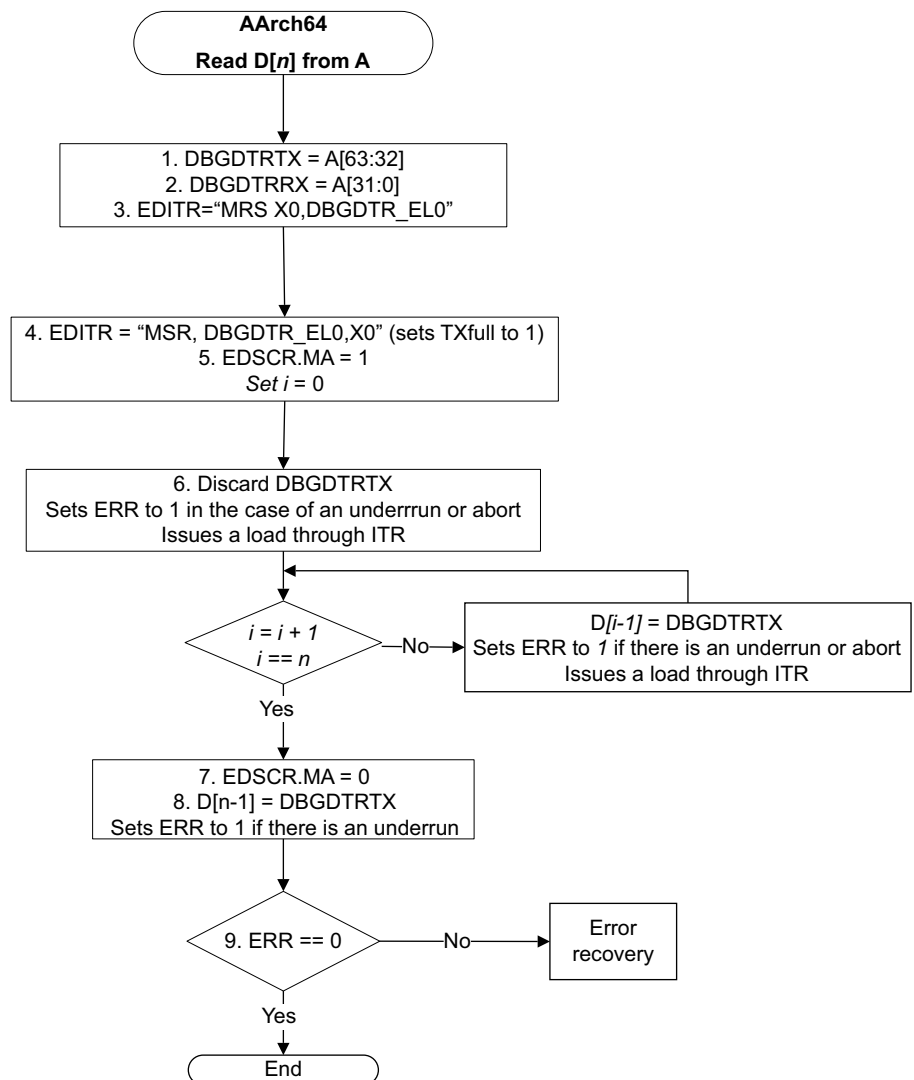

Figure K9-2 Fast data upload in AArch64 state (target to external host)

In Figure K9-2, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
 - a. Write address [31:0] to `DBGDTRRX_EL0`.

- b. Write address [63:32] to `DBGDTRTX_EL0`.
 - c. Write MRS `X0`, `DBGDTR_EL0` to `EDITR`.
 - d. Write MSR `DBGDTR_EL0`, `X0` to `EDITR`. This dummy operation ensures `EDSCR.TXfull == 1`.
 - e. Set `EDSCR.MA` to 1.
 - f. Read `DBGDTRTX_EL0` and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments `X0` by 4.
2. Loop $n-1$ times. From the external debug interface:
 - a. Read `DBGDTRTX_EL0`. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
 - a. Clear `EDSCR.MA` to 0.
 - b. Read `DBGDTRTX_EL0` for the n^{th} value.
 - c. Read `EDSCR` to check for underruns, overruns or Data Aborts during upload.

Appendix K10

Software Usage Examples

This appendix gives software usage examples, for cases where these are likely to contribute significantly to an understanding of the Arm architecture.

It contains the following sections:

- [Use of the Advanced SIMD complex number instructions on page K10-7316.](#)
- [Use of the ARMv8.2 extensions to the Cryptographic Extension on page K10-7318.](#)

K10.1 Use of the Advanced SIMD complex number instructions

[ARMv8.3-CompNum](#) provides instructions to aid floating-point computations of complex numbers. This section illustrates the use of these instructions for complex arithmetic. It is not part of the ARM architecture definition.

This section uses the AArch64 instructions FCADD and FCMLA - usage of the AArch32 instructions VCADD and VCMLA is similar.

When using the instructions implemented by [ARMv8.3-CompNum](#), a complex number is represented in a SIMD&FP register as a pair of adjacent elements, each holding a floating-point number, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number.

K10.1.1 Complex addition

Simple complex addition on a vector of complex numbers is already provided by the vector form of the FADD instruction.

The functionality that FCADD adds is to rotate each complex number in the second vector by 90 degrees or 270 degrees counterclockwise (considering the complex numbers on an Argand diagram) before performing the addition. Mathematically, this is equivalent to multiplying the second complex number by i or $-i$ before addition.

This means, given a complex number z stored in a pair of elements in one vector, and a complex number w stored in the corresponding element pair in another vector:

- FADD calculates $z + w$.
- FCADD calculates $z \pm iw$.

K10.1.2 Complex multiplication

The FCMLA instruction does not provide functionality for complex multiplication directly. However, a pair of FCMLA instructions can provide this function.

The FCMLA instruction operates on corresponding pairs of complex numbers stored in SIMD&FP vector registers, and adds the result to the corresponding complex number in the destination SIMD&FP vector register. This computation is as follows:

1. The second complex number is rotated by 0, 90, 180 or 270 degrees counterclockwise.
2. That complex number is multiplied by either the real or imaginary part of the first complex number:
 - When the rotation is 0 or 180 degrees, the real part is used.
 - When the rotation is 90 or 270 degrees, the imaginary part is used.
3. The resulting complex number is added to the corresponding complex number in the destination register.

Mathematically, considering the complex numbers on an Argand diagram:

- Rotation by 180 degrees is equivalent to negation.
- Rotation by 90 degrees is equivalent to multiplying by i .
- Rotation by 270 degrees is equivalent to multiplying by $-i$.

This means that, for a first complex number z , where $z = a+bi$, and a second complex number w , if initially the corresponding complex number in the destination register is zero:

- When the rotation is 0 degrees the result of the multiply-add is aw .
- When the rotation is 180 degrees, the result is $-aw$.
- When the rotation is 90 degrees, the result is biw .
- When the rotation is 270 degrees, the result is $-biw$.

This means that, if the destination register is zeroed and an FCMLA instruction is executed with a rotation parameter of 0, and then the same instruction is executed with a rotation parameter of 90:

- The first execution returns aw in the destination register.
- The second execution accumulates biw to this, meaning the result is $aw+biw$.
- This result is the product of $(a+bi)w$, which is the product zw .

So, this pair of instructions can be used to implement complex multiplication.

After zeroing $V0$, the syntax of a pair of instructions to perform this complex number multiplication might be:

```
FCMLA V0.4S, V1.4S, V2.4S, #0
FCMLA V0.4S, V1.4S, V2.4S, #90
```

Other simple pairs of FCMLA instructions perform useful computations. For example, considering a first complex number z and second complex number w , defined as before, and a destination register that has been zeroed before the first FCMLA instruction is executed:

1. The following pair of instructions calculates the complex conjugate of z multiplied by w .
FCMLA V0.4S, V1.4S, V2.4S, #0
FCMLA V0.4S, V1.4S, V2.4S, #270
2. The following pair of instructions calculates the negation of z multiplied by w .
FCMLA V0.4S, V1.4S, V2.4S, #180
FCMLA V0.4S, V1.4S, V2.4S, #270
3. The following pair of instructions calculates the negation of the complex conjugate of z multiplied by w .
FCMLA V0.4S, V1.4S, V2.4S, #180
FCMLA V0.4S, V1.4S, V2.4S, #90

———— **Note** ————

For these examples, the following caveats must be considered:

- FCMLA performs a fused multiply-add, meaning there is no intermediate rounding. This lack of intermediate rounding can give unexpected results in some cases. ARM expects that these instructions are only used in situations where the effect of the rounding of these results is not material to the calculation.
- When using the FCMLA instructions, the behavior of $(\infty+\infty i)$ multiplied by $(0+i)$ is $(NaN+NaNi)$, rather than the result expected by ISO C, which is complex ∞ .

K10.2 Use of the ARMv8.2 extensions to the Cryptographic Extension

K10.2.1 Use of the SHA512 instructions

These instructions are implemented when [ARMv8.2-SHA](#) is implemented.

The following code sequence shows the use of the SHA512 instructions to calculate a SHA512 hash iteration of 80 rounds. This code is not fully optimized.

```
// X0 contains the pointer to the bottom of the (padded) 16*64 bytes of message to be
// hashed, with space above the that message to hold a further 64 * 64 bytes of working
// data
// X1 contains the pointer to the 0th element of 80 64-bit constants (in ascending addresses) defined in
the SHA2 specification
// X2 contains a loop variable
// V4,V5,V6, V7 hold VS0 to VS3 respectively
// V8 holds running hash V1
// V9 holds running hash V0
MOV X2, #0
loop1

K10.2.2 Use of the SHA3 instructions

These instructions are implemented when [ARMv8.2-SHA](#) is implemented.

The following code sequence shows the use of the SHA3 instructions to obtain the combined theta, phi, rho and chi operations of a SHA3 iteration. ARM expects the iota operation to be performed using a lookup table.

This code is not fully optimized for multiple iterations.

```

// Input State:
//   x=0  x=1  x=2  x=3  x=4
// y=0 v12 v13 v14 v10 v11
// y=1 v7  v8  v9  v5  v6
// y=2 v2  v3  v4  v0  v1
// y=3 v22 v23 v24 v20 v21
// y=4 v17 v18 v19 v15 v16

Appendix K11

Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

- [Introduction on page K11-7326.](#)
- [Load-Acquire, Store-Release and barriers on page K11-7329.](#)
- [Load-Acquire Exclusive, Store-Release Exclusive and barriers on page K11-7333.](#)
- [Using a mailbox to send an interrupt on page K11-7338.](#)
- [Cache and TLB maintenance instructions and barriers on page K11-7339.](#)
- [ARMv7 compatible approaches for ordering, using DMB and DSB barriers on page K11-7351.](#)

———— **Note** —————

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

K11.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K11.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM), and in this Manual it is described as *Simple sequential execution* of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K11.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

DMB See *Data Memory Barrier (DMB)* on page B2-104.

DSB See *Data Synchronization Barrier (DSB)* on page B2-106.

ISB See *Instruction Synchronization Barrier (ISB)* on page B2-104.

Observer, Completion

See *Definition of the ARMv8 memory model* on page B2-97.

See *Completion and endpoint ordering* on page B2-102.

Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K11.1.3 Conventions

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
  LDR R12, [Rx]
  CMP R12, #1
  BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
loop
  LDA R12, [Rx]      ; load acquire ensures it is ordered before subsequent loads/stores
  CMP R12, #1
  BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
  LDR W12, [Xx]
  CMP W12, #1
  B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
loop
  LDAR W12, [Xx]    ; load acquire ensures it is ordered before subsequent loads/stores
  CMP W12, #1
  B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1...Px refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1...Ex refer to non-caching observers, that do not participate in the coherency protocol, but execute ARMv8 instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

———— Note —————

Throughout this appendix, *ARMv8 instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.

Results are expressed in terms of <agent>:<register>, such as P0:R5. The results can be described as:

Permissible This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

Not permissible Results that the architecture expressly forbids.

Required Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of DMB and DSB instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a DMB ST, that is a barrier to stores only, this is shown by the use of DMB [ST]. This indicates that the ST qualifier can be omitted without affecting the result of the test. In some implementations DMB ST is faster than DMB.

For AArch64 code, the shareability domain of the DMB or DSB must be included. This is shown in this manual using the notation DMB <domain> and DSB <domain> respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
 - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
 - The address held in R3 is in Write-Through Cacheable Normal memory.
 - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
 - When used with an STR instruction, 0x55, 0x66, 0x77, and 0x88 respectively.
 - When used with an LDR instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- [Cache maintenance system instructions on page K13-7440.](#)
- [TLB maintenance system instructions on page K13-7441.](#)

K11.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in [Load-Acquire](#), [Load-AcquirePC](#), and [Store-Release](#) on page B2-108.

The following sections show that most of the examples in sections [Simple ordering and barrier cases](#) on page K11-7351 and [Load-Exclusive, Store-Exclusive and barriers](#) on page K11-7355 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K11.2.1 Message passing

The following sections describe:

- [Resolving weakly-ordered message passing by using Acquire and Release](#).
- [Resolving message passing by the use of Store-Release and address dependency](#) on page K11-7330.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in [Weakly-ordered message passing problem](#) on page K11-7351 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

AArch32

P1

```
STR R5, [R1]           ; sets new data
STL R0, [R2]           ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]           ; sets new data
STLR W0, [X2]          ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P3

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in [Message passing with multiple observers on page K11-7352](#) can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

AArch32

P1

```
STR R5, [R1]           ; sets new data
STL R0, [R2]           ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0       ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                       ; and so is ordered after the flag has been seen
```

AArch64

P1

```
STR W5, [X1]           ; sets new data
STLR W0, [X2]          ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR      ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                       ; and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT([R2]==1)
AND R12, R12, #0       ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                       ; and so is ordered after the flag has been seen
```

AArch64

P3

```
WAIT([X2]==1)
AND W12, W12, WZR      ; R12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                       ; and so is ordered after the flag has been seen
```

K11.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

AArch32

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2]           ; updates base address
```

P2

```
LDR R1, [R2]           ; reads base address
CMP R1, #0             ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

AArch64

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2]         ; updates base address
```

P2

```
LDR X1, [X2]           ; reads base address
CMP X1, #0             ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

K11.2.3 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit DSB barrier instruction is required if it is necessary to ensure memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page K11-7354](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

AArch32

```
P1
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

AArch64

```
P1
    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.

K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using LDREX and STREX).
- Acquire only semantics (using LDAEX and STREX).
- Release only semantics (using LDREX and STLEX).
- Sequentially consistent semantics (using LDAEX and STLEX).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of WFE, by removing the need for a DSB barrier and SEV instruction.

K11.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

———— **Note** ————

The inclusion of AArch32 PLDW instructions or AArch64 PFRM PST* instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

```
Px
    PLDW[R1]          ; preload into cache in unique state
Loop
    LDAEX R5, [R1]    ; read lock with acquire
    CMP R5, #0        ; check if 0
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0      ; test if store succeeded
    BNE Loop          ; retry if not

    ; loads and stores in the critical region can now be performed
```

AArch64

```
Px
    PFRM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop
    LDAXR W5, [X1]      ; read lock with acquire
    CBNZ W5, Loop       ; check if 0
    STXR W5, W0, [X1]   ; attempt to store new value
    CBNZ W5, Loop       ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

K11.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

AArch32

```
Px
; loads and stores in the critical region
MOV R0, #0
STL R0, [R1] ; clear the lock with release semantics
```

AArch64

```
Px
; loads and stores in the critical region
STLR WZR, [X1] ; clear the lock with release semantics
```

K11.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

———— Note —————

- The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.
- The inclusion of AArch32 PLDW instructions or AArch64 PFRM PST* instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

This is shown in the implementation below:

AArch32

```
Px
; R1 holds two 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number
PLDW[R1] ; preload into cache in unique state
Loop1
LDAEX R5, [R1] ; read current and next
ADD R5, R5, #0x10000 ; increment the next number
STREX R6, R5, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop1 ; retry if not
CMP R5, R5, ROR #16 ; is the current ticket ours
BEQ block_start
Loop2
LDAH R6, [R1] ; read current value
```

```

    CMP R6, R5, LSR #16 ; compare it with our allocated ticket
    BNE Loop2           ; retry (spin) if it is not the same
block_start

```

AArch64

Px

```

    ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
    LDAXR W5, [X1]       ; read current and next
    ADD W5, W5, #0x10000 ; increment the next number
    STXR W6, W5, [X1]   ; and update the value
    CBNZ W6, Loop1      ; did the exclusive pass - retry if not

    AND W6, W5, #0xFFFF
    CMP W6, W5, LSR #16 ; is the current ticket ours
    B.EQ block_start

Loop2
    LDARH W6, [X1]      ; read current value
    CMP W6, W5, LSR #16 ; compare it with the our allocated ticket
    B.NE Loop2          ; retry (spin) if it isn't the same
block_start

```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

```

    ADD R6, R6, #1
    STLH R6, [R1]

```

AArch64

```

    ADD W6, W6, #1
    STLRH W6, [X1]

```

K11.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

———— Note ————

The inclusion of AArch32 PLDW instructions or AArch64 PFRM PST* instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

Simple lock

The following is an example of lock acquire code using WFE:

AArch32

Px

```

    PLDW[R1]          ; preload into cache in unique state
Loop
    LDAEX R5, [R1]    ; read lock with acquire
    CMP R5, #0        ; check if 0
    WFENE             ; sleep if the lock is held
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0      ; test if store succeeded
    BNE Loop          ; retry if not
    
```

AArch64

Px

```

    SEVL             ; invalidates the WFE on the first loop iteration
    PRFM PSTL1KEEP, [X1] ; allocate into cache in unique state
Loop
    WFE
    LDAXR W5, [X1]   ; read lock with acquire
    CBNZ W5, Loop    ; check if 0
    STXR W5, W0, [X1] ; attempt to store new value
    CBNZ W5, Loop    ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
    
```

And the following is an example of lock release code:

AArch32

Px

```

    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock
    
```

AArch64

Px

```

    ; loads and stores in the critical region
    STLR WZR, [X1]       ; clear the lock
    
```

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

AArch32

Px

```

    ; R1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]          ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]    ; read current and next
    ADD R5, R5, #0x10000 ; increment the next number
    STREX R6, R5, [R1] ; and update the value
    CMP R6, #0        ; did the exclusive pass
    BNE Loop          ; retry if not
    CMP R5, R5, ROR #16 ; is the current ticket ours
    BEQ block_start
    SEVL
Loop2
    WFE               ; wait if there has not been a change to the count since last
    
```

```
                ; read
    LDAEXH R6, [R1] ; check the current count
    CMP R6, R5, LSR #16 ; check if it is equal
    BNE Loop2
block_start
```

AArch64

Px

```
    ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
    LDAXR W5, [X1] ; read current and next
    ADD W5, W5, #0x10000 ; increment the next number
    STXR W6, W5, [X1] ; and update the value
    CBNZ W6, Loop1 ; did the exclusive pass - retry if not

    AND W6, W5, 0xFFFF
    CMP W6, W5, LSR #16 ; is the current ticket ours
    B.EQ block_start
    SEVL
Loop2
    WFE
    LDAXRH W6, [X1] ; read current value
    CMP W6, W5, LSR #16 ; compare it with our allocated ticket
    B.NE Loop2 ; retry (spin) if it is not the same
block_start
```

K11.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

AArch32

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```

K11.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- [Data cache maintenance instructions](#).
- [Instruction cache maintenance instructions](#) on page K11-7343.
- [TLB maintenance instructions and barriers](#) on page K11-7346.

K11.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- [Message passing to non-caching observers](#).
- [Multiprocessing message passing to non-caching observers](#).
- [Invalidating DMA buffers, non-functional example](#) on page K11-7340.
- [Invalidating DMA buffers, functional example with single PE](#) on page K11-7341.
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page K11-7342.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

```
STR R5, [R1]           ; updates data (assumed to be in P1 cache)
DCCMVAC R1             ; cleans cache to point of coherency
DMB                   ; ensures effects of the clean will be observed before the
                       ; flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1) ; waits for the flag (with order)
LDR R5, [R1]         ; reads the data
```

AArch64

P1

```
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
DC CVAC, X1           ; cleans cache to point of coherency
DMB ISH               ; ensures effects of the clean will be observed before the
                       ; flag is set
STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1) ; waits for the flag (with order)
LDR W5, [X1]         ; reads the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1

```
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
STL R0, [R2]          ; sends a flag for P2 (ordered by the store release)

P2

WAIT ([R2] == 1)      ; waits for P1 flag
DMB                   ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1            ; cleans cache to point of coherency - will clean P1 cache
DMB                   ; ensures effects of the clean will be observed before the
                       ; flag to E1 is set
STR R0, [R4]          ; sends flag to E1

E1

WAIT_ACQ ([R4] == 1) ; waits for P2 flag (ordered)
LDR R5, [R1]          ; reads data
```

AArch64

```
P1

STR W5, [X1]          ; updates data (assumed to be in P1 cache)
STLR W0, [X2]         ; sends a flag for P2 (ordered)

P2

WAIT ([X2] == 1)      ; waits sfor P1 flag
DMB SY                ; ensure cache clean is observed after P1 flag is observed
DC CVAC, X1           ; cleans cache to point of coherency, will clean P1 cache
DMB SY                ; ensures effects of the clean will be observed before the
                       ; flag to E1 is set
STR W0, [X4]          ; sends flag to E1

E1

WAIT_ACQ ([X4] == 1) ; waits for P2 flag
LDR W5, [X1]          ; reads data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

————— Note —————

The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

AArch32

```
P1

DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
                       ; but as the DMA will subsequently overwrite this region an
                       ; invalidate operation is sufficient and usually more efficient
DMB                   ; ensures cache invalidation is observed before the next store
                       ; is observed
STR R0, [R3]          ; sends flag to external agent
WAIT_ACQ ([R4]==1)    ; waits for a different flag from an external agent
LDR R5, [R1]
```

```
E1
    WAIT ([R3] == 1) ; waits for flag
    STR R5, [R1]    ; stores new data
    STL R0, [R4]    ; sends a flag
```

AArch64

```
P1
    DC IVAC, X1 ; ensure cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
    DMB SY      ; ensures cache invalidation is observed before the next store
                ; is observed
    STR W0, [X3] ; sends flag to external agent
    WAIT_ACQ ([X4]==1) ; waits for a different flag from an external agent
    LDR W5, [X1]
```

```
E1
    WAIT ([X3] == 1) ; waits for flag
    STR W5, [X1]    ; stores new data
    STLR W0, [X4]   ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

```
P1
    DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
    DMB        ; ensures cache invalidation is observed before the next store
                ; is observed
    STR R0, [R3] ; sends flag to external agent
    WAIT ([R4]==1) ; waits for a different flag from an external agent
    DMB        ; ensures that cache invalidate is observed after the flag
                ; from external agent is observed
    DCIMVAC R1 ; ensures cache discards stale copies before use
    LDR R5, [R1]
```

```
E1
    WAIT ([R3] == 1) ; waits for flag
    STR R5, [R1]    ; stores new data
    STL R0, [R4]    ; sends a flag
```

AArch64

```
P1
    DC IVAC, X1 ; ensures cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
    DMB SY      ; ensures cache invalidation is observed before the next store
                ; is observed
    STR W0, [X3] ; sends flag to external agent
    WAIT ([X4]==1) ; waits for a different flag from an external agent
    DMB SY      ; ensures that cache invalidate is observed after the flag
                ; from external agent is observed
    DC IVAC, X1 ; ensures cache discards stale copies before use
    LDR W5, [X1]
```

```
E1
```

```
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1] ; stores new data
STLR W0, [X4] ; sends a flag
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

AArch32

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
STL R0, [R2] ; signals release of [R1]
WAIT_ACQ ([R2] == 0) ; waits for new value from DMA
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1 ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3] ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1 ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2] ; signals availability of new [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1] ; sends new [R1]
DMB [ST]
STR R0, [R4] ; indicates that new data is available to P1
```

AArch64

P0

```
(Use data from [X1], potentially using [X1] as scratch space)
STLR W0, [X2] ; signals release of [X1]
WAIT_ACQ ([X2] == 0) ; waits for new value from DMA
LDR W5, [X1]
```

P1

```
WAIT ([X2] == 1) ; waits for release of [R1] by P0
DC IVAC, X1 ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3] ; requests new data for [R1]
WAIT ([X4] == 1) ; waits for new data
DMB SY
DCIMVAC X1 ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2] ; signals availability of new [R1]
```

E1

```
WAIT ([X3] == 1) ; waits for new data request
STR W5, [X1] ; sends new [R1]
STR W0, [X4] ; indicates new data is available to P1
```

In this example, the result $P0:R5 == 0x55$ is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

K11.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor.*
- *Ensuring the visibility of updates to instructions for a multiprocessor.*

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

AArch32

P1

```

STR R11, [R1]      ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1        ; clean to PoU makes the new instruction visible to the instruction cache
DSB
ICIMVAU R1        ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1
DSB               ; ensures completion of the invalidation
ISB               ; ensures instruction fetch path sees new instruction cache state
BX R1

```

In AArch64 state, the branch predictor maintenance is not required.

AArch64

P1

```

STR W11, [X1]     ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1       ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH
IC IVAU, X1       ; ensures instruction cache/branch predictor discards stale data
DSB ISH           ; ensures completion of the invalidation
ISB               ; ensures instruction fetch path sees new instruction cache state
BR X1

```

————— Note —————

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

Ensuring the visibility of updates to instructions for a multiprocessor

The ARMv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

AArch32

P1

```
STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ; ensures completion of the clean on all PEs
ICIMVAU R1 ; ensures instruction cache discards stale data
BPIMVA R ; ensures branch predictor discards stale data
DSB ; ensures completion of the instruction cache and branch predictor
; invalidation on all PEs
STR R0, [R2] ; sets flag to signal completion
ISB ; synchronizes context on this PE
BX R1 ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1) ; waits for flag signalling completion
ISB ; synchronizes context on this PE
BX R1 ; branches to new code
```

AArch64

P1

```
STR X11, [X1] ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH ; ensures completion of the clean on all PEs
IC IVAU, X1 ; ensures instruction cache/branch predictor discards stale data
DSB ISH ; ensures completion of the instruction cache/branch predictor
; invalidation on all PEs
STR W0, [X2] ; sets flag to signal completion
ISB ; synchronizes context on this PE
BR R1 ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1) ; waits for flag signalling completion
ISB ; synchronizes context on this PE
BR X1 ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

```
STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ; ensures completion of the clean on all PEs
ICIMVAU R1 ; ensures instruction cache discards stale data
BPIMVA R1 ; ensures branch predictor discards stale data
DMB ; ensures ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch
; predictor on other PEs
STR R0, [R2] ; sets flag to signal completion
DSB ; ensures completion of the invalidation on all PEs
ISB ; synchronizes context on this PE
BX R1 ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1) ; waits for flag signalling completion
DSB ; this DSB does not guarantee completion of P1
; ICIMVAU/BPIMVA
ISB
BX R1
```

AArch64

P1

```
STR W11, [X1]      ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1        ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH            ; ensures completion of the clean on all PEs
IC IVAU, X1        ; ensures instruction cache/branch predictor discards stale data
DMB ISH            ; ensures ordering of the store after the invalidation
                   ; DOES NOT guarantee completion of instruction cache/branch
                   ; predictor on other PEs
STR W0, [X2]       ; sets flag to signal completion
DSB ISH            ; ensures completion of the invalidation on all PEs
ISB                ; synchronizes context on this PE
BR X1              ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1)   ; waits for flag signalling completion
DSB ISH            ; this DSB does not guarantee completion of P1
                   ; ICIMVAU/BPIMVA
ISB
BR X1
```

In this example, P2...Px might not see the updated region of code at R1.

K11.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- [Ensuring the visibility of updates to translation tables for a uniprocessor.](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor.](#)
- [Paging memory in and out on page K11-7347.](#)
- [Using break-before-make when updating translation table entries on page K11-7348.](#)

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

AArch32

P1

```
STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]      ; updates the translation table entry
DSB ISH            ; ensures visibility of the update to translation table walks
TLBI VAE1, X10     ; assumes we are in the EL1
DSB ISH            ; ensures completion of the TLB invalidation
ISB                ; synchronise context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that executes a TLB maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

AArch32

P1

```

STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; Note ISB is not broadcast and must be executed locally
                  ; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

```

AArch64

P1

```

STR X11, [X1]      ; updates the translation table entry
DSB ISH            ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10
DSB ISH            ; ensures completion of the TLB invalidation
ISB                ; Note ISB is not broadcast and must be executed locally
                  ; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

```

STR R11, [R1]      ; updates the translation table for the region being paged out
DSB                ; ensures visibility of the update to translation table walks
TLBIMVAIS R10      ; invalidates the old entry
DSB                ; ensures completion of the invalidation on all PEs
ISB                ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                ; ensures completion of the memory transfer (this could be part of
                  ; LoadMemoryFromBackingStore)
ICIALLUIS          ; also invalidates the branch predictor
STR R9, [R1]       ; creates a new translation table entry with a new mapping
DSB                ; ensures completion of the instruction cache
                  ; and branch predictor invalidation
                  ; AND ensures visibility of the new translation table mapping

```

```
ISB ; ensures synchronisation of this instruction stream
```

AArch64

P1

```
STR X11, [X1] ; updates the translation table for the region being paged out
DSB ISH ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10 ; invalidates the old entry
DSB ISH ; ensures completion of the invalidation on all PEs
ISB ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore)
IC IALLUIS ; also invalidates the branch predictor
STR X9, [X1] ; creates a new translation table entry with a new mapping
DSB ISH ; ensures completion of the instruction cache
; and branch predictor invalidation
; AND ensures visibility of the new translation table mapping
ISB ; ensures synchronisation of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIAILLUIS` in AArch32 state and `IC IALLUIS` in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` in AArch32 state and `IC IVAU` operations in AArch64 state. This invalidation must be done when the mapping used for the `ICIMVAU` and `IC IVAU` operations is valid but not executable.

Using break-before-make when updating translation table entries

The ARM Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see [Using break-before-make when updating translation table entries on page D5-2516](#) for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE, running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

AArch32

P1

```

; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]      ; stores invalid entry
DSB ISH                ; ensures visibility of the update to translation table walks
TLBIMVAIS R4          ; invalidates the old entry
DSB ISH                ; ensures completion of the invalidation on all PEs
ICIALLUIS             ; also invalidates the branch predictor
STRD R5, R6, [R3]     ; store new mapping
DSB ISH                ; ensures visibility of the update to translation table walks
ISB                    ; ensures synchronisation of this instruction stream

```

———— **Note** ————

This example shows an update to an entry in a translation table that is using the long-descriptor format.

AArch64

P1

```

; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]          ; stores invalid entry
DSB ISH                ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X3      ; invalidates the old entry
DSB ISH                ; ensures completion of the invalidation on all PEs
IC IALLUIS            ; also invalidates the branch predictor
STR X4, [X2]         ; store new mapping
DSB ISH                ; ensures visibility of the update to translation table walks
ISB                    ; ensures synchronisation of this instruction stream

```

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state, and IC IVAU in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

K11.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
- When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped peripheral to the DMA peripheral can be met by the insertion of a DSB <domain> instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

AArch32

```
P1
    STR R5, [R2]      ; data written to the data buffer
    DSB
    STR R0, [R4]      ; R4 contains the address of the DMA control register
```

AArch64

```
P1
    STR W5, [X2]      ; data written to the data buffer
    DSB <domain>
    STR W0, [X4]      ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

AArch32

```
P1
    WAIT ([R4] == 1)  ; R4 contains the address of the status register,
                    ; and the value '1' indicates completion of the DMA transfer
    DSB
    LDR R5, [R2]      ; reads data from the data buffer
```

AArch64

```
P1
    WAIT ([X4] == 1) ; X4 contains the address of the status register,
                    ; and the value '1' indicates completion of the DMA transfer
    DSB <domain>
    LDR W5, [X2]      ; reads data from the data buffer
```

K11.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- [Simple ordering and barrier cases.](#)
- [Load-Exclusive, Store-Exclusive and barriers on page K11-7355.](#)
- [Using a mailbox to send an interrupt on page K11-7357.](#)
- [Cache and TLB maintenance instructions and barriers on page K11-7357.](#)

K11.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- [Weakly-ordered message passing problem.](#)
- [Message passing with multiple observers on page K11-7352.](#)

Weakly-ordered message passing problem

P1

```
STR R5, [R1]           ; sets new data
STR R0, [R2]           ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)         ; waits on flag
LDR R5, [R1]           ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1]           ; sets new data
DMB [ST]               ; ensures all observers observe data before the flag
STR R0, [R2]           ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)         ; waits on flag
```

```
DMB ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]
```

Resolving by the use of barriers and address dependency

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.

Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.

Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K11-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table K11-1 Dependency examples

Address dependency		Control dependency		Address and control dependency ^a
(a)	(b)	(c)	(d)	(e)
LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]
LDR r2, [r1]	AND r1, r1, #0	CMP r1, #55	CMP r1, #55	CMP r1, #0
	LDR r2, [r3, r1]	LDRNE r2, [r3]	MOVNE r4, #22	LDRNE r2, [r1]
			LDR r2, [r3, r4]	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem on page K11-7351* can also be satisfied as shown in the following example:

P1

```
STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

Message passing with multiple observers

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

```

P1
    STR R5, [R1]           ; sets new data
    STR R0, [R2]           ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load is address dependent on R12
                           ; and so is ordered after the flag has been seen

```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

```

P1
    STR R5, [R1]           ; sets new data
    DMB [ST]              ; ensures all observers observe data before the flag
    STR R0, [R2]           ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is the destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is the destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

```

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

```

P1
    STR R5, [R1, #offset] ; sets new data in a field
    DMB [ST]              ; ensures all observers observe data before base address is updated
    STR R1, [R2]           ; updates base address

P2
    LDR R1, [R2]           ; reads for base address
    CMP R1, #0             ; checks if it is valid
    BEQ null_trap
    LDR R5, [R1, #offset] ; uses base address to read field

```

If the `null_trap` is not taken, it is required that P2:R5==0x55. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

```
P1
    STR R0, [R2]
    WAIT ([R3]==1)
```

```
P2
    WAIT ([R2]==1)
    STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a DMB instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

```
P1
    STR R0, [R2]
    DMB
    WAIT ([R3]==1)
```

```
P2
    WAIT ([R2]==1)
    STR R0, [R3]
```

The DMB executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

```
P1
    STR R0, [R2]
    WAIT ([R2]==2)
```

```
P2
    WAIT ([R2]==1)
    LDR R0, [R2]
    ADD R0, R0, #1
    STR R0, [R2]
```

In this example, the same deadlock can occur in ARMv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a DMB instruction prevents this deadlock:

```
P1
    STR R0, [R2]
    DMB
    WAIT ([R2]==2)
```

```
P2
    WAIT ([R2]==1)
    LDR R0, [R2]
```

```
ADD R0, R0, #1
STR R0, [R2]
```

WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page K11-7354](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

```
P1
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

However, if the example in [Posting a store before polling for acknowledgement on page K11-7354](#) is extended to include a WFE, there is no risk of a deadlock. The extended example is:

```
P1
    STR R0, [R2]
    DMB
Loop
    LDR R12, [R3]
    CMP R12, #1
    WFENE
    BNE Loop

P2
    WAIT ([R2]==1)
    STR R0, [R3]
    DSB
    SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see [Use of Wait For Event \(WFE\) and Send Event \(SEV\) with locks on page K11-7356](#).

K11.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in [Synchronization and semaphores on page B2-135](#), are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

```
Px
Loop
LDREX R5, [R1]      ; reads lock
CMP R5, #0          ; checks if 0
STREXEQ R5, R0, [R1] ; attempts to store new value
CMPEQ R5, #0        ; tests if store succeeded
BNE Loop            ; retries if not
DMB                  ; ensures that all subsequent accesses are observed after the
                    ; gaining of the lock is observed
                    ; loads and stores in the critical region can now be performed
```

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

```
Px
                    ; loads and stores in the critical region
MOV R0, #0
DMB                  ; ensures all previous accesses are observed before the lock is cleared
STR R0, [R1]        ; clears the lock
```

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

```
Px
Loop
LDREX R5, [R1]      ; reads lock
CMP R5, #0          ; checks if 0
WFENE                ; sleeps if the lock is held
STREXEQ R5, R0, [R1] ; attempts to store new value
CMPEQ R5, #0        ; tests if store succeeded
BNE Loop            ; retries if not
DMB                  ; ensures that all subsequent accesses are observed after the
                    ; gaining of the lock is observed
                    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using SEV:

```
Px
                    ; loads and stores in the critical region
MOV R0, #0
DMB                  ; ensures all previous accesses are observed before the lock is cleared
```

```

STR R0, [R1]           ; clears the lock
DSB                    ; ensures completion of the store that cleared the lock before
                       ; sending the event
SEV

```

K11.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

```

P1
    STR R5, [R1]           ; message stored to shared memory location
    DSB [ST]
    STR R1, [R4]           ; R4 contains the address of a mailbox

P2
    ; interrupt service routine
    LDR R5, [R1]

```

———— **Note** ————

The DSB executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K11.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- [Data cache maintenance instructions](#).
- [Instruction cache maintenance instructions](#) on page K11-7360.
- [TLB maintenance instructions and barriers](#) on page K11-7361.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- [Message passing to non-caching observers](#).
- [Multiprocessing message passing to non-caching observers](#) on page K11-7358.
- [Invalidating DMA buffers, non-functional example](#) on page K11-7358.
- [Invalidating DMA buffers, functional example with single PE](#) on page K11-7359.
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page K11-7359.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

```

P1
    STR R5, [R1]           ; updates data (assumed to be in P1's cache)
    DCCMVAC R1             ; cleans cache to point of coherency
    DMB                    ; ensures effects of the clean will be observed before the flag is set
    STR R0, [R4]           ; sends flag to external agent (Non-cacheable location)

```

```
E1
    WAIT ([R4] == 1)      ; waits for the flag
    DMB                  ; ensures that flag has been seen before reading data
    LDR R5, [R1]         ; reads the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

```
P1
    STR R5, [R1]         ; updates data (assumed to be in P1's cache)
    DMB [ST]            ; ensures new data is observed before the flag to P2 is set
    STR R0, [R2]         ; sends flag to P2

P2
    WAIT ([R2] == 1)    ; waits for flag from P1
    DMB                 ; ensures cache clean is observed after P1 flag is observed
    DCCMVA R1           ; cleans cache to point of coherency - this cleans the cache of P1
    DMB                 ; ensures effects of the clean are observed before the flag to E1 is set
    STR R0, [R4]        ; sends flag to E1

E1
    WAIT ([R4] == 1)    ; waits for flag from P2
    DMB                 ; ensures that flag has been observed before reading the data
    LDR R5, [R1]        ; reads the data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

```
P1
    DCIMVA R1           ; ensures caches are not dirty. A clean operation could be
                        ; used but the DMA overwrites this region so an invalidate operation
                        ; is sufficient and usually more efficient
    DMB                 ; ensures cache invalidation is observed before the next store is observed
    STR R0, [R3]        ; sends flag to external agent
    WAIT ([R4]==1)      ; waits for a different flag from an external agent
    DMB                 ; observes flag from external agent before reading new data. However [R1]
                        ; could have been brought into cache earlier
    LDR R5, [R1]

E1
    WAIT ([R3] == 1)    ; waits for flag
    STR R5, [R1]        ; stores new data
    DMB
    STR R0, [R4]        ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

```

P1
    DCIMVAC R1           ; ensures cache is not dirty. A clean operation could be
                        ; used but the DMA overwrites this region so an invalidate operation
                        ; is sufficient and usually more efficient
    DMB                 ; ensures cache invalidation is observed before the next store is observed
    STR R0, [R3]        ; sends flag to external agent
    WAIT ([R4]==1)     ; waits for a different flag from an external agent
    DMB                 ; ensures that cache invalidate is observed after the flag
                        ; from external agent is observed
    DCIMVAC R1         ; ensures cache discards stale copies before use
    LDR R5, [R1]

E1
    WAIT ([R3] == 1)    ; waits for flag
    STR R5, [R1]        ; stores new data
    DMB [ST]
    STR R0, [R4]        ; sends a flag
  
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

```

P0
    (Use data from [R1], potentially using [R1] as scratch space)
    DMB
    STR R0, [R2]        ; signals release of [R1]
    WAIT ([R2] == 0)   ; waits for new value from DMA
    DMB
    LDR R5, [R1]

P1
    WAIT ([R2] == 1)   ; waits for release of [R1] by P0
    DCIMVAC R1        ; ensures caches are not dirty, invalidate is sufficient
    DMB
    STR R0, [R3]      ; requests new data for [R1]
    WAIT ([R4] == 1) ; waits for new data
    DMB
    DCIMVAC R1        ; ensures caches discard stale copies before use
    DMB
    MOV R0, #0
    STR R0, [R2]      ; signals availability of new [R1]

E1
    WAIT ([R3] == 1)   ; waits for new data request
    STR R5, [R1]       ; sends new [R1]
    DMB [ST]
    STR R0, [R4]       ; indicates new data available to P1
  
```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- [Ensuring the visibility of updates to instructions for a uniprocessor.](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor.](#)

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensures instruction cache and branch predictor discard stale data
ICIMVAU R1              ; ensures instruction cache and branch predictor discard stale data
BPIMVA R1               ; ensures instruction cache and branch predictor discard stale data
DSB                     ; ensures completion of the invalidation
ISB                     ; ensures instruction fetch path observes new instruction cache state
BX R1
```

Ensuring the visibility of updates to instructions for a multiprocessor

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensures completion of the clean on all processors
ICIMVAU R1              ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1               ; ensures instruction cache/branch predictor discards stale data
DSB                     ; ensures completion of the instruction cache and branch predictor
                       ; invalidation on all PEs
STR R0, [R2]           ; sets flag to signal completion
ISB                     ; synchronizes context on this PE
BX R1                   ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1)       ; waits for flag signaling completion
ISB                     ; synchronizes context on this processor
BX R1                   ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
```

```

DSB                ; ensure completion of the clean on all PEs
ICIMVAU R1        ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB                ; ensure ordering of the store after the invalidation
                  ; DOES NOT guarantee completion of instruction cache/branch
                  ; predictor on other PEs
STR R0, [R2]      ; sets flag to signal completion
DSB                ; ensures completion of the invalidation on all PEs
ISB                ; synchronizes context on this PE
BX R1              ; branches to new code
    
```

P2-Px

```

WAIT ([R2] == 1)   ; waits for flag signaling completion
DSB                ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1
    
```

In this example, P2...Px might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- [Ensuring the visibility of updates to translation tables for a uniprocessor.](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page K11-7362.](#)
- [Paging memory in and out on page K11-7362.](#)

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

P1

```

STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; synchronizes context on this PE
;
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed
    
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1]          ; updates the translation table entry
DSB                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                    ; ensures completion of the BP and TLB invalidation
ISB                    ; Note ISB is not broadcast and must be executed locally on other PEs
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]          ; updates the translation table for the region being paged out
DSB                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R10          ; invalidates the old entry
DSB                    ; ensures completion of the invalidation on all processors
ISB                    ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                    ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore
ICIAILLUIS             ; also invalidates the branch predictor
STR R9, [R1]           ; creates a new translation table entry with a new mapping
DSB                    ; ensures completion of instruction cache and branch predictor invalidation
; and ensures visibility of the new translation table mapping
ISB                    ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIALUIS` to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` operations. This invalidation must be done when the mapping used for the `ICIMVAU` operations is valid but not executable.

Appendix K12

ARM Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some *helper* procedures and functions that are used by pseudocode. It contains the following sections:

- *About the ARM pseudocode* on page K12-7366.
- *Pseudocode for instruction descriptions* on page K12-7367.
- *Data types* on page K12-7369.
- *Operators* on page K12-7374.
- *Statements and control structures* on page K12-7380.
- *Built-in functions* on page K12-7385.
- *Miscellaneous helper procedures and functions* on page K12-7388.
- *ARM pseudocode definition index* on page K12-7390.

Note

This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of ARM pseudocode. This appendix is not complete. Changes are planned for future releases.

K12.1 About the ARM pseudocode

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. [Pseudocode for instruction descriptions on page K12-7367](#) gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- [Data types on page K12-7369](#).
- [Operators on page K12-7374](#).
- [Statements and control structures on page K12-7380](#).

[Built-in functions on page K12-7385](#) and [Miscellaneous helper procedures and functions on page K12-7388](#) describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. [ARM pseudocode definition index on page K12-7390](#) contains the indexes to the pseudocode.

K12.1.1 General limitations of ARM pseudocode

The pseudocode statements IMPLEMENTATION_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

For more information, see [Special statements on page K12-7384](#).

K12.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in [General limitations of ARM pseudocode on page K12-7366](#) and [Limitations of the instruction pseudocode on page K12-7368](#).

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. [Instruction encoding diagrams and instruction pseudocode](#) gives more information about the pseudocode provided for each instruction.

K12.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed()` then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is `CONSTRAINED UNPREDICTABLE`. For more information, see [SBZ or SBO fields T32 and A32 in instructions on page K1-7198](#).
- A named single bit or a bit in a named multi-bit field. The `cond` field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a `cond` field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a `cond` field in bits[31:28], and bits[31:28] of the instruction are not `0b1111`.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and `UNDEFINED`, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.
3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns `TRUE` if all instruction bits or fields with the same name as its argument have the same value, and `FALSE` otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is `CONSTRAINED UNPREDICTABLE`. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as `CONSTRAINED UNPREDICTABLE`, see [SBZ or SBO fields T32 and A32 in instructions on page K1-7198](#).
5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

K12.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see [Ordering constraints on page E2-3566](#).
- Pseudocode does not describe the exact rules when an `UNDEFINED` instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then ...` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a `NOP`. [Conditional execution of undefined instructions on page G1-5276](#) describes the exact rules.
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. [Combinations of floating-point exceptions on page E1-3546](#) describes the exact rules.

————— **Note** —————

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an `LDM` instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-5239](#).

K12.3 Data types

This section describes:

- [General data type rules](#).
- [Bitstrings](#).
- [Integers](#) on page K12-7370.
- [Reals](#) on page K12-7370.
- [Booleans](#) on page K12-7370.
- [Enumerations](#) on page K12-7371.
- [Structures](#) on page K12-7371.
- [Tuples](#) on page K12-7372.
- [Arrays](#) on page K12-7373.

K12.3.1 General data type rules

ARM architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

```
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named `count` is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K12.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

`bits(N)` The type name of a bitstring of length `N`.
`bit` A synonym of `bits(1)`.

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.

Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right $N-1$ to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit $N-1$ is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length N is bit $(N-1)$ and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

K12.3.3 Integers

This section describes the data type for integer numbers.

Syntax

`integer` The type name for the integer data type.

Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer +2³¹. If -2³¹ needs to be written in hexadecimal, it must be written as -0x80000000.

K12.3.4 Reals

This section describes the data type for real numbers.

Syntax

`real` The type name for the real data type.

Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.

K12.3.5 Booleans

This section describes the Boolean data type.

Syntax

`boolean` The type name for the Boolean data type.

TRUE The two values a Boolean variable can take.

Description

A Boolean is a logical TRUE or FALSE value.

———— **Note** —————

This is not the same type as `bit`, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

K12.3.6 Enumerations

This section describes the enumeration data type.

Syntax and examples

`enumeration` Keyword to defined a new enumeration type.

```
enumeration Example {Example_One, Example_Two, Example_Three};
```

A definition of a new enumeration called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

Description

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

K12.3.7 Structures

This section describes the structure data type.

Syntax and examples

`type` The keyword used to declare the structure data type.

```
type ShiftSpec is (bits(2) shift, integer amount)
```

An example definition for a new structure called `ShiftSpec` that contains an bitstring member called `shift` and a integer member named `amount`. Structure definitions must not be terminated with a semicolon.

```
ShiftSpec abc;
```

A declaration of a variable named `abc` of type `ShiftSpec`.

```
abc.shift
```

Syntax to refer to the individual members within the structure variable.

Description

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

In the syntax section, the example defines a structure called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer named `amount`. After declaring a variable of that type named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

K12.3.8 Tuples

This section describes the tuple data type.

Examples

```
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.

K12.3.9 Arrays

This section describes the array data type.

Syntax

array The type name for the array data type.

```
array data_type array_name[A..B];
```

Declaration of an array of type `data_type`, which might be compound data type. It is named `array_name` and is indexed with an integer range from A to B.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See [Function and procedure calls on page K12-7380](#).

K12.4 Operators

This section describes:

- [Relational operators](#).
- [Boolean operators](#).
- [Bitstring operators on page K12-7375](#).
- [Arithmetic operators on page K12-7375](#).
- [The assignment operator on page K12-7376](#).
- [Precedence rules on page K12-7378](#).
- [Conditional expressions on page K12-7378](#).
- [Operator polymorphism on page K12-7378](#).

K12.4.1 Relational operators

The following operations yield results of type `boolean`.

Equality and non-equality

If two variables `x` and `y` are of the same type, their values can be tested for equality by using the expression `x == y` and for non-equality by using the expression `x != y`. In both cases, the result is of type `boolean`.

Both `x` and `y` must be of type `bits(N)`, `real`, `enumeration`, `boolean`, or `integer`. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a `d==15` test.

A special form of comparison is defined with a bitstring literal that can contain bit values `'0'`, `'1'`, and `'x'`. Any bit with value `'x'` is ignored in determining the result of the comparison. For example, if `opcode` is a 4-bit bitstring, the expression `opcode == '1x0x'` matches the values `'1000'`, `'1100'`, `'1001'`, and `'1101'`. This is known as a bitmask.

————— **Note** —————

This special form is permitted in the implied equality comparisons in the `when` parts of `case ... of ...` structures.

Comparisons

If `x` and `y` are integers or reals, then `x < y`, `x <= y`, `x > y`, and `x >= y` are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with `IN`

`<expression> IN {<set>}` produces `TRUE` if `<expression>` is a member of `<set>`. Otherwise, it is `FALSE`. `<set>` must be a list of expressions separated by commas.

K12.4.2 Boolean operators

If `x` is a Boolean expression, then `!x` is its logical inverse.

If `x` and `y` are Boolean expressions, then `x && y` is the result of ANDing them together. As in the C language, if `x` is `FALSE`, the result is determined to be `FALSE` without evaluating `y`.

————— **Note** —————

This is known as short circuit evaluation.

If `x` and `y` are booleans, then `x || y` is the result of ORing them together. As in the C language, if `x` is `TRUE`, the result is determined to be `TRUE` without evaluating `y`.

———— **Note** ————

If x and y are booleans or Boolean expressions, then the result of $x != y$ is the same as the result of exclusive-ORing x and y together. The operator EOR only accepts bitstring arguments.

K12.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

Logical operations on bitstrings

If x is a bitstring, NOT(x) is the bitstring of the same length obtained by logically inverting every bit of x .

If x and y are bitstrings of the same length, x AND y , x OR y , and x EOR y are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of x and y together.

Bitstring concatenation and slicing

If x and y are bitstrings of lengths N and M respectively, then $x:y$ is the bitstring of length $N+M$ constructed by concatenating x and y in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is $x<integer_list>$, where x is the integer or bitstring being sliced, and $<integer_list>$ is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in $<integer_list>$. In $x<integer_list>$, each of the integers in $<integer_list>$ must be:

- ≥ 0 .
- $< \text{Len}(x)$ if x is a bitstring.

The definition of $x<integer_list>$ depends on whether $integer_list$ contains more than one integer:

- If $integer_list$ contains more than one integer, $x<i, j, k, \dots, n>$ is defined to be the concatenation:
 $x<i> : x<j> : x<k> : \dots : x<n>$.
- If $integer_list$ consists of just one integer i , $x<i>$ is defined to be:
 - If x is a bitstring, '0' if bit i of x is a zero and '1' if bit i of x is a one.
 - If x is an integer, and y is the unique integer in the range 0 to $2^{i+1}-1$ that is congruent to x modulo 2^{i+1} . Then $x<i>$ is '0' if $y < 2^i$ and '1' if $y \geq 2^i$.

Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

The notation for a range expression is $i:j$ with $i \geq j$ is shorthand for the integers in order from i down to j , with both end values included. For example, $instr<31:28>$ represents $instr<31, 30, 29, 28>$.

$x<integer_list>$ is assignable provided x is an assignable bitstring and no integer appears more than once in $<integer_list>$. In particular, $x<i>$ is assignable if x is an assignable bitstring and $0 \leq i < \text{Len}(x)$.

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as N. In such cases, the syntax APSR.N is used as a more readable synonym for APSR<31> as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR.<N, C, Q> is synonymous with APSR <31, 29, 27>.

K12.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

Unary plus and minus

If x is an integer or real, then $+x$ is x unchanged, $-x$ is x with its sign reversed. Both are of the same type as x .

Addition and subtraction

If x and y are integers or reals, $x+y$ and $x-y$ are their sum and difference. Both are of type integer if x and y are both of type integer, and real otherwise.

There are two cases where the types of x and y can be different. A bitstring and an integer can be added together to allow the operation $PC + 4$. An integer can be subtracted from a bitstring to allow the operation $PC - 2$.

If x and y are bitstrings of the same length N , so that $N = \text{Len}(x) = \text{Len}(y)$, then $x+y$ and $x-y$ are the least significant N bits of the results of converting x and y to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

$$\begin{aligned}x+y &= (\text{SInt}(x) + \text{SInt}(y))\langle N-1:0 \rangle \\ &= (\text{UInt}(x) + \text{UInt}(y))\langle N-1:0 \rangle \\ x-y &= (\text{SInt}(x) - \text{SInt}(y))\langle N-1:0 \rangle \\ &= (\text{UInt}(x) - \text{UInt}(y))\langle N-1:0 \rangle\end{aligned}$$

If x is a bitstring of length N and y is an integer, $x+y$ and $x-y$ are the bitstrings of length N defined by $x+y = x + y\langle N-1:0 \rangle$ and $x-y = x - y\langle N-1:0 \rangle$. Similarly, if x is an integer and y is a bitstring of length M , $x+y$ and $x-y$ are the bitstrings of length M defined by $x+y = x\langle M-1:0 \rangle + y$ and $x-y = x\langle M-1:0 \rangle - y$.

Multiplication

If x and y are integers or reals, then $x * y$ is the product of x and y . It is of type integer if x and y are both of type integer, and real otherwise.

Division and modulo

If x and y are reals, then x/y is the result of dividing x by y , and is always of type real.

If x and y are integers, then $x \text{ DIV } y$ and $x \text{ MOD } y$ are defined by:

$$\begin{aligned}x \text{ DIV } y &= \text{RoundDown}(x/y) \\ x \text{ MOD } y &= x - y * (x \text{ DIV } y)\end{aligned}$$

It is a pseudocode error to use any of x/y , $x \text{ MOD } y$, or $x \text{ DIV } y$ in any context where y can be zero.

Scaling

If x and n are of type integer, then:

- $x \ll n = \text{RoundDown}(x * 2^n)$.
- $x \gg n = \text{RoundDown}(x * 2^{(-n)})$.

Raising to a power

If x is an integer or a real and n is an integer then x^n is the result of raising x to the power of n , and:

- If x is of type integer then x^n is of type integer.
- If x is of type real then x^n is of type real.

K12.4.5 The assignment operator

The assignment operator is the $=$ character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

This following subsection defines valid expression syntax.

General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word UNKNOWN preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an ARM architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

———— Note ————

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.
The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

———— Note ————

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
 - An optional preceding data type name.
 - A data type the variable was given earlier in the pseudocode by recursive application of this rule.

- A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

K12.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see [Boolean operators on page K12-7374](#).
2. Operators on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if i , j and k are integer variables, $i > 0 \ \&\& \ j > 0 \ \&\& \ k > 0$ is acceptable, but $i > 0 \ \&\& \ j > 0 \ || \ k > 0$ is not.

K12.4.7 Conditional expressions

If x and y are two values of the same type and t is a value of type `boolean`, then `if t then x else y` is an expression of the same type as x and y that produces x if t is `TRUE` and y if t is `FALSE`.

K12.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator `+` has forms that act on various combinations of integers, reals and bitstrings.

[Table K12-1](#) summarizes the operand types valid for each unary operator and the result type. [Table K12-2 on page K12-7379](#) summarizes the operand types valid for each binary operator and the result type.

Table K12-1 Result and operand types permitted for unary operators

Operator	Operand Type	Result Type
-	integer	integer
	real	real
NOT	bits(N)	bits(N)
!	boolean	boolean

Table K12-2 Result and operand types permitted for binary operators

Operator	First operand type	Second operand type	Result type
==	bits(N)	integer	boolean
		bits(N)	
	integer	integer	
	real	real	
	enumeration	enumeration	
!=	boolean	boolean	boolean
	bits(N)	bits(N)	
	integer	integer	
<, >	real	real	boolean
	enumeration	enumeration	
+, -	integer	integer	integer
	real	real	real
	bits(N)	bits(N) integer	bits(N)
<=, >=	integer	integer	integer
	real	real	real
	bits(N)	bits(N)	bits(N)
/	integer	integer	integer
	real	real	real
DIV	integer	integer	integer
	bits(N)	integer	integer
MOD	boolean	boolean	boolean
	bits(N)	bits(N)	bits(N)
&&,	integer	integer	integer
	real	integer	real
AND, OR, EOR	integer	integer	integer
	real	integer	real
^	integer	integer	integer
	real	integer	real

K12.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- [Statements and Indentation](#).
- [Function and procedure calls](#).
- [Conditional control structures](#) on page K12-7382.
- [Loop control structures](#) on page K12-7383.
- [Special statements](#) on page K12-7384.
- [Comments](#) on page K12-7384.

K12.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as `if ... then ... else ...` or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K12.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.

Procedure and function definitions

A procedure definition has the form:

```
<procedure name>(<argument prototypes>)
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

Note

A function or procedure name can include a ".". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```
<return type> <function name>[<argument prototypes>]
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```
<function name>[<argument prototypes>] = <value prototype>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

```
<procedure_name>(<arguments>;
```

Return statements

A procedure return has the form:

```
return;
```

A function return has the form:

```
return <expression>;
```

where <expression> is of the type declared in the function prototype line.

K12.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

```
if <boolean_expression> then
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

elsif <boolean_expression> then
    <statement a>;
    <statement b>;
    ...
    <statement z>;
else
    <statement A>;
    <statement B>;
    ...
    <statement Z>;
```

The block of lines consisting of `elsif` and its indented statements is optional, and multiple `elsif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when the `then` part, and in the `else` part if it is present, contain only simple statements such as:

```
if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

Note

In these forms, <statement 1>, <statement 2> and <statement A> must be terminated by semicolons. This and the fact that the `else` part is optional distinguish its use as a control structure from its use as a ternary operator.

case ... of ...

A case ... of ... structure has the form:

```
case <expression> of
    when <literal values1>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;

    when <literal values2>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;

    ... more "when" groups if required ...
```

```

otherwise
  <statement A>;
  <statement B>;
  ...
  <statement Z>;

```

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional when groups in the structure. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details see [Equality and non-equality on page K12-7374](#).

K12.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

repeat ... until ...

A repeat ... until ... structure has the form:

```

repeat
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
until <boolean_expression>;

```

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

while ... do

A while ... do structure has the form:

```

while <boolean_expression> do
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;

```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

for ...

A for ... structure has the form:

```

for <assignable_expression> = <integer_expr1> to <integer_expr2>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;

```

The <assignable_expression> is initialized to <integer_expr1> and compared to <integer_expr2>. If <integer_expr1> is less than <integer_expr2>, the loop body is executed and the <assignable_expression> incremented by one. This repeats until <assignable expression> is more than or equal to <integer_expr2>.

There is an alternate form:

```

for <assignable_expression> = <integer_expr1> downto <integer_expr2>

```

where <integer_expr1> is decremented after the loop body executes and continues until <assignable expression> is less than or equal than <integer_expr2>.

K12.5.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

UNDEFINED

This subsection describes the statement:

```
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE...

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

```
IMPLEMENTATION_DEFINED {"<text>"};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION_DEFINED. An optional <text> field can give more information.

K12.5.6 Comments

The pseudocode supports two styles of comments:

- `//` starts a comment that is terminated by the end of the line.
- `/*` starts a comment that is terminated by `*/`.

`/**/` statements might not be nested, and the first `*/` ends the comment.

———— **Note** —————

Comment lines do not require a terminating semicolon.

K12.6 Built-in functions

This section describes:

- [Bitstring manipulation functions](#).
- [Arithmetic functions on page K12-7386](#).

K12.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

Bitstring length and most significant bit

If x is a bitstring:

- The bitstring length function $\text{Len}(x)$ returns the length of x as an integer.

Bitstring concatenation and replication

If x is a bitstring and n is an integer with $n \geq 0$:

- $\text{Replicate}(x, n)$ is the bitstring of length $n \cdot \text{Len}(x)$ consisting of n copies of x concatenated together.
- $\text{Zeros}(n) = \text{Replicate}('0', n)$.
- $\text{Ones}(n) = \text{Replicate}('1', n)$.

Bitstring count

If x is a bitstring, $\text{BitCount}(x)$ is an integer result equal to the number of bits of x that are ones.

Testing a bitstring for being all zero or all ones

If x is a bitstring:

- $\text{IsZero}(x)$ produces TRUE if all of the bits of x are zeros and FALSE if any of them are ones
- $\text{IsZeroBit}(x)$ produces '1' if all of the bits of x are zeros and '0' if any of them are ones.

$\text{IsOnes}(x)$ and $\text{IsOnesBit}(x)$ work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)   = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

Lowest and highest set bits of a bitstring

If x is a bitstring, and $N = \text{Len}(x)$:

- $\text{LowestSetBit}(x)$ is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, $\text{LowestSetBit}(x) = N$.
- $\text{HighestSetBit}(x)$ is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, $\text{HighestSetBit}(x) = -1$.
- $\text{CountLeadingZeroBits}(x)$ is the number of zero bits at the left end of x , in the range 0 to N . This means:
 $\text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x)$.
- $\text{CountLeadingSignBits}(x)$ is the number of copies of the sign bit of x at the left end of x , excluding the sign bit itself, and is in the range 0 to $N-1$. This means:
 $\text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(x \ll N-1 : 1 \gg \text{EOR } x \ll N-2 : 0 \gg)$.

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then $\text{ZeroExtend}(x, i)$ is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if $i = \text{Len}(x)$, then $\text{ZeroExtend}(x, i) = x$, and if $i > \text{Len}(x)$, then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If x is a bitstring and i is an integer, then $\text{SignExtend}(x, i)$ is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if $i = \text{Len}(x)$, then $\text{SignExtend}(x, i) = x$, and if $i > \text{Len}(x)$, then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either $\text{ZeroExtend}(x, i)$ or $\text{SignExtend}(x, i)$ in a context where it is possible that $i < \text{Len}(x)$.

Converting bitstrings to integers

If x is a bitstring, $\text{SInt}()$ is the integer whose two's complement representation is x .

$\text{UInt}()$ is the integer whose unsigned representation is x .

$\text{Int}(x, \text{unsigned})$ returns either $\text{SInt}(x)$ or $\text{UInt}(x)$ depending on the value of its second argument.

K12.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, $\text{Abs}(x)$ returns the absolute value of x . The result is the same type as x .

Rounding and aligning

If x is a real:

- $\text{RoundDown}(x)$ produces the largest integer n such that $n \leq x$.
- $\text{RoundUp}(x)$ produces the smallest integer n such that $n \geq x$.
- $\text{RoundTowardsZero}(x)$ produces:
 - $\text{RoundDown}(x)$ if $x > 0.0$.
 - 0 if $x == 0.0$.
 - $\text{RoundUp}(x)$ if $x < 0.0$.

If x and y are both of type integer, $\text{Align}(x, y) = y * (x \text{ DIV } y)$, and is of type integer.

If x is of type bitstring and y is of type integer, $\text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y)) \langle \text{Len}(x) - 1 : 0 \rangle$, and is a bitstring of the same length as x .

It is a pseudocode error to use either form of $\text{Align}(x, y)$ in any context where y can be 0. In practice, $\text{Align}(x, y)$ is only used with y a constant power of two, and the bitstring form used with $y = 2^n$ has the effect of producing its argument with its n low-order bits forced to zero.

Maximum and minimum

If x and y are integers or reals, then $\text{Max}(x, y)$ and $\text{Min}(x, y)$ are their maximum and minimum respectively. x and y must both be of type integer or of type real. The function returns a value of the same type as its operands.

K12.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous *helper* procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

———— **Note** —————

[Chapter J1 *ARMv8 Pseudocode*](#) also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in [Chapter J1](#) this section will be removed from the manual.

K12.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

```
EndOfInstruction();
```

K12.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

```
Hint_Debug(bits(4) option);
```

K12.7.3 Hint_PreloadData()

This procedure performs a *preload data* hint.

```
Hint_PreloadData(bits(32) address);
```

K12.7.4 Hint_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

```
Hint_PreloadDataForWrite(bits(32) address);
```

K12.7.5 Hint_PreloadInstr()

This procedure performs a *preload instructions* hint.

```
Hint_PreloadInstr(bits(32) address);
```

K12.7.6 Hint_Yield()

This procedure performs a *yield* hint.

```
Hint_Yield();
```

K12.7.7 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an External abort and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsExternalAbort(Fault type)  
    assert type != Fault_None;
```

```
boolean IsExternalAbort(FaultRecord fault);
```

K12.7.8 IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsAsyncAbort(Fault type)
    assert type != Fault_None;

boolean IsAsyncAbort(FaultRecord fault);
```

K12.7.9 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the HSR.

```
bits(11) LSInstructionSyndrome();
```

K12.7.10 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```
integer ProcessorID();
```

K12.7.11 RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

```
boolean RemapRegsHaveResetValues();
```

K12.7.12 ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally-defined reset values to those values. For more information about the affected registers see:

- [PE state on reset to AArch64 state on page D1-2167.](#)
- [PE state on reset into AArch32 state on page G1-5297.](#)

```
AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)
```

K12.7.13 ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

```
bits(32) ThisInstr();
```

———— **Note** —————

Currently, this function is used only on 32-bit instruction encodings.

K12.7.14 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```
integer ThisInstrLength();
```

K12.8 ARM pseudocode definition index

This section contains the following tables:

- [Table K12-3](#) which contains the pseudocode data types.
- [Table K12-4](#) which contains the pseudocode operators.
- [Table K12-5 on page K12-7391](#) which contains the pseudocode keywords and control structures.
- [Table K12-6 on page K12-7392](#) which contains the statements with special behaviors.

Table K12-3 Index of pseudocode data types

Keyword	Meaning
array	Type name for the array type
bit	Keyword equivalent to bits(1)
bits(N)	Type name for the bitstring of length N data type
boolean	Type name for the Boolean data type
enumeration	Keyword to define a new enumeration type
integer	Type name for the integer data type
real	Type name for the real data type
type	Keyword to define a new structure

Table K12-4 Index of pseudocode operators

Operator	Meaning
-	Unary minus on integers or reals
	Subtraction of integers, reals and bitstrings
	Used in the left-hand side of an assignment or a tuple to discard the result
+	Unary plus on integers or reals
	Addition of integers, reals and bitstrings
.	Extract named member from a list
	Extract named bit or field from a register
:	Bitstring concatenation
	Integer range in bitstring extraction operator
!	Boolean NOT
!=	Comparison for inequality
(...)	Around arguments of procedure or function
[...]	Around array index
	Around arguments of array-like function
*	Multiplication of integers, reals, and bitstrings
/	Division of reals

Table K12-4 Index of pseudocode operators (continued)

Operator	Meaning
&&	Boolean AND
<	<i>Less than</i> comparison of integers and reals
<...>	Slicing of specified bits of bitstring or integer
<<	Multiply integer by power of 2
<=	<i>Less than or equal</i> comparison of integers and reals
=	Assignment operator
==	Comparison for equality
>	<i>Greater than</i> comparison of integers and reals
>=	<i>Greater than or equal</i> comparison of integers and reals
>>	Divide integer by power of 2
	Boolean OR
^	Exponential operator
AND	Bitwise AND of bitstrings
DIV	Quotient from integer division
EOR	Bitwise EOR of bitstrings
IN	Tests membership of a certain expression in a set of values
MOD	Remainder from integer division
NOT	Bitwise inversion of bitstrings
OR	Bitwise OR of bitstrings
case ... of ...	Control structure for the
if ... then ... else ...	Condition expression selecting between two values

Table K12-5 Index of pseudocode keywords and control structures

Operator	Meaning
/*...*/	Comment delimiters
//	Introduces comment terminated by end of line
FALSE	One of two values a Boolean can take (other than TRUE)
for ... = ...to ...	Loop control structure, counting up from the initial value to the upper limit
for ... = ... downto ...	Loop control structure, counting down from the initial value to the lower limit
if ... then ... else ...	Conditional control structure
otherwise	Introduces default case in case ... of ... control structure

Table K12-5 Index of pseudocode keywords and control structures (continued)

Operator	Meaning
repeat ... until ...	Loop control structure that runs at least once until the termination condition is satisfied
return	Procedure or function return
TRUE	One of two values a Boolean can take (other than FALSE)
when	Introduces specific case in case ... of ... control structure
while ... do ...	Loop control structure that runs until the termination condition is satisfied

Table K12-6 Index of special statements

Keyword	Meaning
IMPLEMENTATION_DEFINED	Describes IMPLEMENTATION DEFINED behavior
SEE	Points to other pseudocode to use instead
UNDEFINED	Cause Undefined Instruction exception
UNKNOWN	Unspecified value
UNPREDICTABLE	Unspecified behavior

Appendix K13

Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation* on page K13-7394.
- *Alphabetical index of AArch64 registers and System instructions* on page K13-7399.
- *Functional index of AArch64 registers and System instructions* on page K13-7412.
- *Alphabetical index of AArch32 registers and System instructions* on page K13-7426.
- *Functional index of AArch32 registers and System instructions* on page K13-7435.
- *Alphabetical index of memory-mapped registers* on page K13-7446.
- *Functional index of memory-mapped registers* on page K13-7452.

K13.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, `_EL0`, `_EL1`, `_EL2`, or `_EL3`.

The following sections disambiguate the general register names:

- [Register name disambiguation by Execution state.](#)
- [Register name disambiguation by Exception level on page K13-7398.](#)

K13.1.1 Register name disambiguation by Execution state

Table K13-1 disambiguates the general names of the registers by Execution state.

Table K13-1 Disambiguation of general names of registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>

CCSIDR_EL1	<i>CCSIDR_EL1, Current Cache Size ID Register on page D12-2734</i>
CLIDR_EL1	<i>CLIDR_EL1, Cache Level ID Register on page D12-2737</i>
CNTFRQ_EL0	<i>CNTFRQ_EL0, Counter-timer Frequency register on page D12-3442</i>
CNTHCTL_EL2	<i>CNTHCTL_EL2, Counter-timer Hypervisor Control register on page D12-3444</i>
CNTHP_CTL_EL2	<i>CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register on page D12-3450</i>
CNTHP_CVAL_EL2	<i>CNTHP_CVAL_EL2, Counter-timer Physical Timer CompareValue register (EL2) on page D12-3453</i>
CNTHP_TVAL_EL2	<i>CNTHP_TVAL_EL2, Counter-timer Physical Timer TimerValue register (EL2) on page D12-3455</i>
CNTHPS_CTL_EL2	<i>CNTHPS_CTL_EL2, Counter-timer Secure Physical Timer Control register (EL2) on page D12-3458</i>
CNTHPS_CVAL_EL2	<i>CNTHPS_CVAL_EL2, Counter-timer Secure Physical Timer CompareValue register (EL2) on page D12-3460</i>

Table K13-6 Alphabetical index of AArch64 Registers (continued)

Register	Description, see
CNTHPS_TVAL_EL2	<i>CNTHPS_TVAL_EL2</i> , Counter-timer Secure Physical Timer TimerValue register (EL2) on page D12-3462
CNTHV_CTL_EL2	<i>CNTHV_CTL_EL2</i> , Counter-timer Virtual Timer Control register (EL2) on page D12-3464
CNTHV_CVAL_EL2	<i>CNTHV_CVAL_EL2</i> , Counter-timer Virtual Timer CompareValue register (EL2) on page D12-3467
CNTHV_TVAL_EL2	<i>CNTHV_TVAL_EL2</i> , Counter-timer Virtual Timer TimerValue Register (EL2) on page D12-3470
CNTHVS_CTL_EL2	<i>CNTHVS_CTL_EL2</i> , Counter-timer Secure Virtual Timer Control register (EL2) on page D12-3473
CNTHVS_CVAL_EL2	<i>CNTHVS_CVAL_EL2</i> , Counter-timer Secure Virtual Timer CompareValue register (EL2) on page D12-3476
CNTHVS_TVAL_EL2	<i>CNTHVS_TVAL_EL2</i> , Counter-timer Secure Virtual Timer TimerValue register (EL2) on page D12-3478
CNTKCTL_EL1	<i>CNTKCTL_EL1</i> , Counter-timer Kernel Control register on page D12-3480
CNTP_CTL_EL0	<i>CNTP_CTL_EL0</i> , Counter-timer Physical Timer Control register on page D12-3484
CNTP_CVAL_EL0	<i>CNTP_CVAL_EL0</i> , Counter-timer Physical Timer CompareValue register on page D12-3490
CNTP_TVAL_EL0	<i>CNTP_TVAL_EL0</i> , Counter-timer Physical Timer TimerValue register on page D12-3496
CNTPCT_EL0	<i>CNTPCT_EL0</i> , Counter-timer Physical Count register on page D12-3500
CNTPS_CTL_EL1	<i>CNTPS_CTL_EL1</i> , Counter-timer Physical Secure Timer Control register on page D12-3502
CNTPS_CVAL_EL1	<i>CNTPS_CVAL_EL1</i> , Counter-timer Physical Secure Timer CompareValue register on page D12-3504
CNTPS_TVAL_EL1	<i>CNTPS_TVAL_EL1</i> , Counter-timer Physical Secure Timer TimerValue register on page D12-3506
CNTV_CTL_EL0	<i>CNTV_CTL_EL0</i> , Counter-timer Virtual Timer Control register on page D12-3508
CNTV_CVAL_EL0	<i>CNTV_CVAL_EL0</i> , Counter-timer Virtual Timer CompareValue register on page D12-3514
CNTV_TVAL_EL0	<i>CNTV_TVAL_EL0</i> , Counter-timer Virtual Timer TimerValue register on page D12-3519
CNTVCT_EL0	<i>CNTVCT_EL0</i> , Counter-timer Virtual Count register on page D12-3523
CNTVOFF_EL2	<i>CNTVOFF_EL2</i> , Counter-timer Virtual Offset register on page D12-3525
CONTEXTIDR_EL1	<i>CONTEXTIDR_EL1</i> , Context ID Register (EL1) on page D12-2739
CONTEXTIDR_EL2	<i>CONTEXTIDR_EL2</i> , Context ID Register (EL2) on page D12-2743
CPACR_EL1	<i>CPACR_EL1</i> , Architectural Feature Access Control Register on page D12-2746
CPTR_EL2	<i>CPTR_EL2</i> , Architectural Feature Trap Register (EL2) on page D12-2751
CPTR_EL3	<i>CPTR_EL3</i> , Architectural Feature Trap Register (EL3) on page D12-2758
CSSELR_EL1	<i>CSSELR_EL1</i> , Cache Size Selection Register on page D12-2761
CTR_EL0	<i>CTR_EL0</i> , Cache Type Register on page D12-2763
CurrentEL	<i>CurrentEL</i> , Current Exception Level on page C5-351
DACR32_EL2	<i>DACR32_EL2</i> , Domain Access Control Register on page D12-2766

Table K13-6 Alphabetical index of AArch64 Registers (continued)

Register	Description, see
DAIF	<i>DAIF, Interrupt Mask Bits</i> on page C5-353
DBGAUTHSTATUS_EL1	<i>DBGAUTHSTATUS_EL1, Debug Authentication Status register</i> on page D12-3211
DBGBCR<n>_EL1	<i>DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15</i> on page D12-3214
DBGBVR<n>_EL1	<i>DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15</i> on page D12-3218
DBGCLAIMCLR_EL1	<i>DBGCLAIMCLR_EL1, Debug Claim Tag Clear register</i> on page D12-3223
DBGCLAIMSET_EL1	<i>DBGCLAIMSET_EL1, Debug Claim Tag Set register</i> on page D12-3225
DBGDTR_EL0	<i>DBGDTR_EL0, Debug Data Transfer Register; half-duplex</i> on page D12-3227
DBGDTRRX_EL0	<i>DBGDTRRX_EL0, Debug Data Transfer Register; Receive</i> on page D12-3229
DBGDTRTX_EL0	<i>DBGDTRTX_EL0, Debug Data Transfer Register; Transmit</i> on page D12-3231
DBGPRCR_EL1	<i>DBGPRCR_EL1, Debug Power Control Register</i> on page D12-3233
DBGVCR32_EL2	<i>DBGVCR32_EL2, Debug Vector Catch Register</i> on page D12-3235
DBGWCR<n>_EL1	<i>DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15</i> on page D12-3239
DBGWVR<n>_EL1	<i>DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15</i> on page D12-3243
DC CISW	<i>DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way</i> on page C5-430
DC CIVAC	<i>DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC</i> on page C5-432
DC CSW	<i>DC CSW, Data or unified Cache line Clean by Set/Way</i> on page C5-434
DC CVAC	<i>DC CVAC, Data or unified Cache line Clean by VA to PoC</i> on page C5-436
DC CVAP	<i>DC CVAP, Data or unified Cache line Clean by VA to PoP</i> on page C5-438
DC CVAU	<i>DC CVAU, Data or unified Cache line Clean by VA to PoU</i> on page C5-440
DC ISW	<i>DC ISW, Data or unified Cache line Invalidate by Set/Way</i> on page C5-442
DC IVAC	<i>DC IVAC, Data or unified Cache line Invalidate by VA to PoC</i> on page C5-444
DC ZVA	<i>DC ZVA, Data Cache Zero by VA</i> on page C5-446
DCZID_EL0	<i>DCZID_EL0, Data Cache Zero ID register</i> on page D12-2768
DISR_EL1	<i>DISR_EL1, Deferred Interrupt Status Register</i> on page D12-3405
DIT	<i>DIT, Data Independent Timing</i> on page C5-356
DLR_EL0	<i>DLR_EL0, Debug Link Register</i> on page D12-3245
DSPSR_EL0	<i>DSPSR_EL0, Debug Saved Program Status Register</i> on page D12-3246

K13.3 Functional index of AArch64 registers and System instructions

This section is an index of the AArch64 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- *Special-purpose registers.*
- *VMSA-specific registers* on page K13-7413.
- *ID registers* on page K13-7414.
- *Performance monitors registers* on page K13-7415.
- *Debug registers* on page K13-7416.
- *Generic timer registers* on page K13-7417.
- *Cache maintenance system instructions* on page K13-7417.
- *Address translation system instructions* on page K13-7418.
- *TLB maintenance system instructions* on page K13-7419.
- *Base system registers* on page K13-7421.

K13.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

Table K13-7 Special-purpose registers

Register	Description, see
DLR_EL0	DLR_EL0
ELR_EL1	ELR_EL1
ELR_EL2	ELR_EL2
ELR_EL3	ELR_EL3
SP_EL0	SP_EL0
SP_EL1	SP_EL1
SP_EL2	SP_EL2
SP_EL3	SP_EL3
SPSR_abt	SPSR_abt
SPSR_EL1	SPSR_EL1
SPSR_EL2	SPSR_EL2
SPSR_EL3	SPSR_EL3
SPSR_fiq	SPSR_fiq
SPSR_irq	SPSR_irq
SPSR_und	SPSR_und

K13.3.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table K13-8 VMSA-specific registers

Register	Description, see
AMAIR_EL1	AMAIR_EL1
AMAIR_EL2	AMAIR_EL2
AMAIR_EL3	AMAIR_EL3
CONTEXTIDR_EL1	CONTEXTIDR_EL1
CONTEXTIDR_EL2	CONTEXTIDR_EL2

K13.3.6 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

Table K13-12 Generic timer registers

Register	Description, see
CNTRQ_EL0	CNTRQ_EL0
CNTHV_CTL_EL2	CNTHV_CTL_EL2
CNTHV_CVAL_EL2	CNTHV_CVAL_EL2
CNTHV_TVAL_EL2	CNTHV_TVAL_EL2
CNTHVS_CTL_EL2	CNTHVS_CTL_EL2
CNTHVS_CVAL_EL2	CNTHVS_CVAL_EL2
CNTHVS_TVAL_EL2	CNTHVS_TVAL_EL2
CNTKCTL_EL1	CNTKCTL_EL1
CNTP_CTL_EL0	CNTP_CTL_EL0
CNTP_CVAL_EL0	CNTP_CVAL_EL0
CNTP_TVAL_EL0	CNTP_TVAL_EL0
CNTPCT_EL0	CNTPCT_EL0
CNTPS_CTL_EL1	CNTPS_CTL_EL1
CNTPS_CVAL_EL1	CNTPS_CVAL_EL1
CNTPS_TVAL_EL1	CNTPS_TVAL_EL1
CNTV_CTL_EL0	CNTV_CTL_EL0
CNTV_CVAL_EL0	CNTV_CVAL_EL0
CNTV_TVAL_EL0	CNTV_TVAL_EL0
CNTVCT_EL0	CNTVCT_EL0

K13.3.7 Cache maintenance system instructions

This section is an index to the registers in the Cache maintenance instructions functional group.

Table K13-13 Cache maintenance system instructions

Register	Description, see
DC CISW	DC CISW
DC CIVAC	DC CIVAC
DC CSW	DC CSW
DC CVAC	DC CVAC
DC CVAP	DC CVAP
DC CVAU	DC CVAU

Table K13-13 Cache maintenance system instructions (continued)

Register	Description, see
DC ISW	DC ISW
DC IVAC	DC IVAC
DC ZVA	DC ZVA
IC IALLU	IC IALLU
IC IALLUIS	IC IALLUIS
IC IVAU	IC IVAU

K13.3.8 Address translation system instructions

This section is an index to the registers in the Address translation instructions functional group.

Table K13-14 Address translation system instructions

Register	Description, see
AT S12E0R	AT S12E0R
AT S12E0W	AT S12E0W
AT S12E1R	AT S12E1R
AT S12E1W	AT S12E1W
AT S1E0R	AT S1E0R
AT S1E0W	AT S1E0W
AT S1E1R	AT S1E1R
AT S1E1RP	AT S1E1RP

AMUSERENR	<i>AMUSERENR, Activity Monitors User Enable Register</i> on page G8-6309
APSR	<i>APSR, Application Program Status Register</i> on page G8-5660
ATS12NSOPR	<i>ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read</i> on page G8-5662
ATS12NSOPW	<i>ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write</i> on page G8-5664
ATS12NSOUR	<i>ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read</i> on page G8-5666
ATS12NSOUW	<i>ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write</i> on page G8-5668
ATS1CPR	<i>ATS1CPR, Address Translate Stage 1 Current state PL1 Read</i> on page G8-5670
ATS1CPRP	<i>ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN</i> on page G8-5672
ATS1CPW	<i>ATS1CPW, Address Translate Stage 1 Current state PL1 Write</i> on page G8-5674
ATS1CPWP	<i>ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN</i> on page G8-5676
ATS1CUR	<i>ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read</i> on page G8-5678

Table K13-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
ATSICUW	<i>ATSICUW, Address Translate Stage 1 Current state Unprivileged Write</i> on page G8-5680
ATS1HR	<i>ATS1HR, Address Translate Stage 1 Hyp mode Read</i> on page G8-5682
ATS1HW	<i>ATS1HW, Address Translate Stage 1 Hyp mode Write</i> on page G8-5684
BPIALL	<i>BPIALL, Branch Predictor Invalidate All</i> on page G8-5686
BPIALLIS	<i>BPIALLIS, Branch Predictor Invalidate All, Inner Shareable</i> on page G8-5688
BPIMVA	<i>BPIMVA, Branch Predictor Invalidate by VA</i> on page G8-5690
CCSIDR	<i>CCSIDR, Current Cache Size ID Register</i> on page G8-5692
CCSIDR2	<i>CCSIDR2, Current Cache Size ID Register 2</i> on page G8-5695
CLIDR	<i>CLIDR, Cache Level ID Register</i> on page G8-5697
CNTFRQ	<i>CNTFRQ, Counter-timer Frequency register</i> on page G8-6357
CNTHCTL	<i>CNTHCTL, Counter-timer Hyp Control register</i> on page G8-6359
CNTHP_CTL	<i>CNTHP_CTL, Counter-timer Hyp Physical Timer Control register</i> on page G8-6361
CNTHP_CVAL	<i>CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register</i> on page G8-6364
CNTHP_TVAL	<i>CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register</i> on page G8-6366
CNTHPS_CTL	<i>CNTHPS_CTL, Counter-timer Secure Physical Timer Control Register (EL2)</i> on page G8-6368
CNTHPS_CVAL	<i>CNTHPS_CVAL, Counter-timer Secure Physical Timer CompareValue Register (EL2)</i> on page G8-6370
CNTHPS_TVAL	<i>CNTHPS_TVAL, Counter-timer Secure Physical Timer TimerValue Register (EL2)</i> on page G8-6371
CNTHV_CTL	<i>CNTHV_CTL, Counter-timer Virtual Timer Control register (EL2)</i> on page G8-6372
CNTHV_CVAL	<i>CNTHV_CVAL, Counter-timer Virtual Timer CompareValue register (EL2)</i> on page G8-6375
CNTHV_TVAL	<i>CNTHV_TVAL, Counter-timer Virtual Timer TimerValue register (EL2)</i> on page G8-6377
CNTHVS_CTL	<i>CNTHVS_CTL, Counter-timer Secure Virtual Timer Control Register (EL2)</i> on page G8-6379
CNTHVS_CVAL	<i>CNTHVS_CVAL, Counter-timer Secure Virtual Timer CompareValue Register (EL2)</i> on page G8-6381
CNTHVS_TVAL	<i>CNTHVS_TVAL, Counter-timer Secure Virtual Timer TimerValue Register (EL2)</i> on page G8-6382
CNTKCTL	<i>CNTKCTL, Counter-timer Kernel Control register</i> on page G8-6383
CNTP_CTL	<i>CNTP_CTL, Counter-timer Physical Timer Control register</i> on page G8-6386
CNTP_CVAL	<i>CNTP_CVAL, Counter-timer Physical Timer CompareValue register</i> on page G8-6390
CNTP_TVAL	<i>CNTP_TVAL, Counter-timer Physical Timer TimerValue register</i> on page G8-6393
CNTPCT	<i>CNTPCT, Counter-timer Physical Count register</i> on page G8-6396
CNTV_CTL	<i>CNTV_CTL, Counter-timer Virtual Timer Control register</i> on page G8-6398
CNTV_CVAL	<i>CNTV_CVAL, Counter-timer Virtual Timer CompareValue register</i> on page G8-6401

Table K13-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
CNTV_TVAL	<i>CNTV_TVAL</i> , Counter-timer Virtual Timer TimerValue register on page G8-6403
CNTVCT	<i>CNTVCT</i> , Counter-timer Virtual Count register on page G8-6405
CNTVOFF	<i>CNTVOFF</i> , Counter-timer Virtual Offset register on page G8-6407
CONTEXTIDR	<i>CONTEXTIDR</i> , Context ID Register on page G8-5699
CP15DMB	<i>CP15DMB</i> , Data Memory Barrier System instruction on page G8-5702
CP15DSB	<i>CP15DSB</i> , Data Synchronization Barrier System instruction on page G8-5704
CP15ISB	<i>CP15ISB</i> , Instruction Synchronization Barrier System instruction on page G8-5706
CPACR	<i>CPACR</i> , Architectural Feature Access Control Register on page G8-5708
CPSR	<i>CPSR</i> , Current Program Status Register on page G8-5712
CSSELR	<i>CSSELR</i> , Cache Size Selection Register on page G8-5716
CTR	<i>CTR</i> , Cache Type Register on page G8-5719
DACR	<i>DACR</i> , Domain Access Control Register on page G8-5722
DBGAUTHSTATUS	<i>DBGAUTHSTATUS</i> , Debug Authentication Status register on page G8-6131
DBGBCR<n>	<i>DBGBCR<n></i> , Debug Breakpoint Control Registers, $n = 0 - 15$ on page G8-6134
DBGBVR<n>	<i>DBGBVR<n></i> , Debug Breakpoint Value Registers, $n = 0 - 15$ on page G8-6138
DBGBXVR<n>	<i>DBGBXVR<n></i> , Debug Breakpoint Extended Value Registers, $n = 0 - 15$ on page G8-6141
DBGCLAIMCLR	<i>DBGCLAIMCLR</i> , Debug Claim Tag Clear register on page G8-6144
DBGCLAIMSET	<i>DBGCLAIMSET</i> , Debug Claim Tag Set register on page G8-6146
DBGDCCINT	<i>DBGDCCINT</i> , DCC Interrupt Enable Register on page G8-6148
DBGDEVID	<i>DBGDEVID</i> , Debug Device ID register 0 on page G8-6150
DBGDEVID1	<i>DBGDEVID1</i> , Debug Device ID register 1 on page G8-6153
DBGDEVID2	<i>DBGDEVID2</i> , Debug Device ID register 2 on page G8-6155
DBGDIDR	<i>DBGDIDR</i> , Debug ID Register on page G8-6157
DBGDRAR	<i>DBGDRAR</i> , Debug ROM Address Register on page G8-6160
DBGDSAR	<i>DBGDSAR</i> , Debug Self Address Register on page G8-6164
DBGDSCRext	<i>DBGDSCRext</i> , Debug Status and Control Register, External View on page G8-6166
DBGDSCRint	<i>DBGDSCRint</i> , Debug Status and Control Register, Internal View on page G8-6171
DBGDTRRText	<i>DBGDTRRText</i> , Debug OS Lock Data Transfer Register, Receive, External View on page G8-6174
DBGDTRRXint	<i>DBGDTRRXint</i> , Debug Data Transfer Register, Receive on page G8-6176
DBGDTRTXext	<i>DBGDTRTXext</i> , Debug OS Lock Data Transfer Register, Transmit on page G8-6178
DBGDTRTXint	<i>DBGDTRTXint</i> , Debug Data Transfer Register, Transmit on page G8-6180
DBGOSDLR	<i>DBGOSDLR</i> , Debug OS Double Lock Register on page G8-6182

Table K13-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
DBGOSECCR	<i>DBGOSECCR, Debug OS Lock Exception Catch Control Register on page G8-6184</i>
DBGOSLAR	<i>DBGOSLAR, Debug OS Lock Access Register on page G8-6186</i>
DBGOSLSR	<i>DBGOSLSR, Debug OS Lock Status Register on page G8-6188</i>
DBGPRCR	<i>DBGPRCR, Debug Power Control Register on page G8-6190</i>
DBGVCR	<i>DBGVCR, Debug Vector Catch Register on page G8-6192</i>
DBGWCR<n>	<i>DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15 on page G8-6198</i>
DBGWFAR	<i>DBGWFAR, Debug Watchpoint Fault Address Register on page G8-6202</i>
DBGWVR<n>	<i>DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15 on page G8-6204</i>
DCCIMVAC	<i>DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC on page G8-5724</i>
DCCISW	<i>DCCISW, Data Cache line Clean and Invalidate by Set/Way on page G8-5726</i>
DCCMVAC	<i>DCCMVAC, Data Cache line Clean by VA to PoC on page G8-5728</i>
DCCMVAU	<i>DCCMVAU, Data Cache line Clean by VA to PoU on page G8-5730</i>
DCCSW	<i>DCCSW, Data Cache line Clean by Set/Way on page G8-5732</i>
DCIMVAC	<i>DCIMVAC, Data Cache line Invalidate by VA to PoC on page G8-5734</i>
DCISW	<i>DCISW, Data Cache line Invalidate by Set/Way on page G8-5736</i>
DFAR	<i>DFAR, Data Fault Address Register on page G8-5738</i>
DFSR	<i>DFSR, Data Fault Status Register on page G8-5740</i>
DISR	<i>DISR, Deferred Interrupt Status Register on page G8-6312</i>
DLR	<i>DLR, Debug Link Register on page G8-6206</i>
DSPSR	<i>DSPSR, Debug Saved Program Status Register on page G8-6208</i>
DTLBIALL	<i>DTLBIALL, Data TLB Invalidate All on page G8-5748</i>
DTLBIASID	<i>DTLBIASID, Data TLB Invalidate by ASID match on page G8-5750</i>
DTLBIMVA	<i>DTLBIMVA, Data TLB Invalidate by VA on page G8-5752</i>
ELR_hyp	<i>ELR_hyp, Exception Link Register (Hyp mode) on page G8-5754</i>
ERRIDR	<i>ERRIDR, Error Record ID Register on page G8-6316</i>
ERRSELR	<i>ERRSELR, Error Record Select Register on page G8-6318</i>
ERXADDR	<i>ERXADDR, Selected Error Record Address Register on page G8-6320</i>
ERXADDR2	<i>ERXADDR2, Selected Error Record Address Register 2 on page G8-6322</i>
ERXCTLR	<i>ERXCTLR, Selected Error Record Control Register on page G8-6324</i>
ERXCTLR2	<i>ERXCTLR2, Selected Error Record Control Register 2 on page G8-6326</i>
ERXFR	<i>ERXFR, Selected Error Record Feature Register on page G8-6328</i>
ERXFR2	<i>ERXFR2, Selected Error Record Feature Register 2 on page G8-6330</i>

K13.5 Functional index of AArch32 registers and System instructions

This section is an index of the AArch32 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- [Special-purpose registers.](#)
- [VMSA-specific registers.](#)
- [ID registers on page K13-7436.](#)
- [Performance monitors registers on page K13-7437.](#)
- [Debug registers on page K13-7438.](#)
- [Generic timer registers on page K13-7439.](#)
- [Cache maintenance system instructions on page K13-7440.](#)
- [Address translation system instructions on page K13-7440.](#)
- [TLB maintenance system instructions on page K13-7441.](#)
- [Legacy feature registers and system instructions on page K13-7442.](#)
- [Base system registers on page K13-7442.](#)

K13.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

Table K13-18 Special-purpose registers

Register	Description, see
DLR	DLR
DSPSR	DSPSR
ELR_hyp	ELR_hyp
SPSR	SPSR
SPSR_abt	SPSR_abt
SPSR_fiq	SPSR_fiq
SPSR_hyp	SPSR_hyp
SPSR_irq	SPSR_irq
SPSR_mon	SPSR_mon
SPSR_svc	SPSR_svc
SPSR_und	SPSR_und

K13.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table K13-19 VMSA-specific registers

Register	Description, see
AMAIRO	AMAIRO
AMAIR1	AMAIR1
CONTEXTIDR	CONTEXTIDR

Table K13-19 VMSA-specific registers (continued)

Register	Description, see
DACR	DACR
HAMAIR0	HAMAIR0
HAMAIR1	HAMAIR1
HMAIR0	HMAIR0
HMAIR1	HMAIR1
HTCR	HTCR
HTTBR	HTTBR
MAIR0	MAIR0
MAIR1	MAIR1
NMRR	NMRR
PRRR	PRRR
TBCCR	TBCCR
TBCCR2	TBCCR2
TTBR0	TTBR0
TTBR1	TTBR1
VTCR	VTCR
VTTBR	VTTBR

K13.5.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table K13-20 ID registers

Register	Description, see
CCSIDR	CCSIDR
CCSIDR2	CCSIDR2
CLIDR	CLIDR
CSSELR	CSSELR
CTR	CTR
ID_AFR0	ID_AFR0
ID_DFR0	ID_DFR0
ID_ISAR0	ID_ISAR0
ID_ISAR1	ID_ISAR1
ID_ISAR2	ID_ISAR2

Table K13-20 ID registers (continued)

Register	Description, see
ID_ISAR3	ID_ISAR3
ID_ISAR4	ID_ISAR4
ID_ISAR5	ID_ISAR5
ID_ISAR6	ID_ISAR6
ID_MMFR0	ID_MMFR0
ID_MMFR1	ID_MMFR1
ID_MMFR2	ID_MMFR2
ID_MMFR3	ID_MMFR3
ID_MMFR4	ID_MMFR4
ID_PFR0	ID_PFR0
ID_PFR1	ID_PFR1
ID_PFR2	ID_PFR2
MIDR	MIDR
MPIDR	MPIDR
REVIDR	REVIDR
TCMTR	TCMTR
TLBTR	TLBTR

K13.5.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table K13-21 Performance monitors registers

Register	Description, see
PMCCFILTR	PMCCFILTR
PMCCNTR	PMCCNTR
PMCEID0	PMCEID0
PMCEID1	PMCEID1
PMCEID2	PMCEID2
PMCEID3	PMCEID3
PMCNTENCLR	PMCNTENCLR
PMCNTENSET	PMCNTENSET
PMCR	PMCR
PMEVCNTR<n>	PMEVCNTR<n>

Table K13-21 Performance monitors registers (continued)

Register	Description, see
PMEVTYPER<n>	PMEVTYPER<n>
PMINTENCLR	PMINTENCLR
PMINTENSET	PMINTENSET
PMMIR	PMMIR
PMOVSRR	PMOVSRR
PMOVSSET	PMOVSSET
PMSELR	PMSELR
PMSWINC	PMSWINC
PMUSERENR	PMUSERENR
PMXEVCNTR	PMXEVCNTR
PMXEVTYPER	PMXEVTYPER

K13.5.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table K13-22 Debug registers

Register	Description, see
DBGAUTHSTATUS	DBGAUTHSTATUS
DBGBCR<n>	DBGBCR<n>
DBGBVR<n>	DBGBVR<n>
DBGBXVR<n>	DBGBXVR<n>
DBGCLAIMCLR	DBGCLAIMCLR
DBGCLAIMSET	DBGCLAIMSET
DBGDCCINT	DBGDCCINT
DBGDEVID	DBGDEVID
DBGDEVID1	DBGDEVID1
DBGDEVID2	DBGDEVID2
DBGDIDR	DBGDIDR
DBGDRAR	DBGDRAR
DBGDSAR	DBGDSAR

K13.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group. Each of the following sections lists the registers for a functional group:

- [ID registers](#).
- [Performance monitors registers](#).
- [Debug registers on page K13-7454](#).
- [Cross-trigger interface registers on page K13-7455](#).
- [Cross-trigger interface registers on page K13-7455](#).

K13.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

Table K13-30 ID registers

Register	Description, see
EDAA32PFR	EDAA32PFR
EDDFR	EDDFR
EDPFR	EDPFR
MIDR_EL1	MIDR_EL1

K13.7.2 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table K13-31 Performance monitors registers

Register	Description, see
PMAUTHSTATUS	PMAUTHSTATUS
PMCCFILTR_EL0	PMCCFILTR_EL0
PMCCNTR_EL0	PMCCNTR_EL0
PMCEID0	PMCEID0
PMCEID1	PMCEID1
PMCEID2	PMCEID2
PMCEID3	PMCEID3
PMCFGR	PMCFGR
PMCID1SR	PMCID1SR
PMCID2SR	PMCID2SR
PMCIDR0	PMCIDR0
PMCIDR1	PMCIDR1
PMCIDR2	PMCIDR2
PMCIDR3	PMCIDR3

CTIPIDR4	CTIPIDR4
CTITRIGINSTATUS	CTITRIGINSTATUS
CTITRIGOUTSTATUS	CTITRIGOUTSTATUS

Glossary

- A32 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.
- A32 instructions were previously called ARM instructions.
- See also* [A32 state](#), [A64 instruction](#), [T32 instruction](#).
- A32 state** The AArch32 Instruction set state in which the PE executes A32 instructions.
- A32 state was previously called ARM state.
- See also* [T32 instruction](#), [T32 state](#).
- A64 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.
- See also* [A32 instruction](#), [T32 instruction](#).
- AArch32** The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets
- See also* [AArch64](#), [A32 instruction](#), [T32 instruction](#).
- AArch64** The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.
- See also* [AArch32](#), [A64 instruction](#).
- Abort** An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.
- Addressing mode** Means a method for generating the memory address used by a load/store instruction.
- Advanced SIMD** A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.

- Aligned** A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.
- An aligned access is one where the address of the access is aligned to the size of each element of the access.
- Architecturally executed** An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.
- In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.
- See also [Condition code check](#), [Simple sequential execution](#).
- Architecturally mapped** Where this manual describes a register as being *architecturally mapped* to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.
- Architecturally UNKNOWN** An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of [UNKNOWN](#). Implementations can define the value of the field, but are not required to do so.
- See also [IMPLEMENTATION DEFINED](#).
- ARM core registers** Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:
- The 13 general-purpose registers, R0-R12, that software can use for processing.
 - SP, the *stack pointer*, that can also be referred to as R13.
 - LR, the *link register*, that can also be referred to as R14.
 - PC, the *program counter*, that can also be referred to as R15.
- See also [General-purpose registers](#).
- ARM instruction** See [A32 instruction](#).
- Associativity** See [Cache associativity](#).
- Atomicity** Describes either single-copy atomicity or multi-copy atomicity. [Atomicity in the Arm architecture on page B2-92](#) defines these forms of atomicity for the ARM architecture.
- See also [Multi-copy atomicity](#), [Single-copy atomicity](#).
- Banked register** A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.
- Base register** A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.
- Base register writeback** Describes writing back a modified value to the base register used in an address calculation.
- Behaves as if** Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.
- Big-endian memory** Means that, for example:
- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.

- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also [Endianness](#), [Little-endian memory](#).

Blocking

Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also [Prefetching](#).

Breakpoint

A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte

An 8-bit data item.

Cache associativity

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

Cache level

The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information, see [Terms used in describing the cache maintenance instructions on page D4-2360](#).

Cache line

The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss

A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets

Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way

A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

Coherence order

See [Coherent](#).

Coherent

Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the *coherence order* for that byte in memory.

Condition code check

The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of [PSTATE.IT](#) determines whether the instruction is executed normally.

See also [Condition code field](#), [Condition flags](#), [Conditional execution](#).

Condition code field

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also [Condition code check](#).

Condition flags The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

See also [Condition code check](#), [PSTATE](#).

Conditional execution

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP.

See also [Condition code check](#).

CONSTRAINED UNPREDICTABLE

Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also [UNPREDICTABLE](#).

Context switch

The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

Context synchronization event

One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a DCPS instruction.
- Executing a DRPS instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All completed changes to the translation tables for entries that, before the change, were not permitted to be cached in a TLB, affect all instruction fetches that appear in program order after the instruction causing the Context synchronization event.
- All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
- In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

- Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

Note

- The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that the performance monitor counters are permitted to reveal such speculation.
 - *Context synchronization events* were previously described as *context synchronization operations*.
-

Data independent timing (DIT)

The time that it takes to execute a piece of code where the time is not a function of the data being operated on. For more information, see [About PSTATE.DIT on page B1-87](#) and [About the DIT bit on page E1-3540](#).

Debugger

In most of this manual, *debugger* refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:

- [Definition of a debugger in the context of self-hosted debug on page D2-2282](#).
- [Definition of a debugger in the context of self-hosted debug on page G2-5350](#).
- [Definition and constraints of a debugger in the context of external debug on page H1-6412](#).

Deprecated

Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.

See also [OPTIONAL](#).

Digital signal processing (DSP)

Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)

An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

Direct read

A direct read of a System register is a read performed by a System register access instruction.

For more information, see [Direct read on page D12-2677](#).

See also [Direct write](#), [Indirect read](#), [Indirect write](#).

Direct write

A direct write of a System register is a write performed by a System register access instruction.

For more information, see [Direct write on page D12-2677](#).

See also [Direct read](#), [Indirect read](#), [Indirect write](#).

DMA

See [Direct Memory Access \(DMA\)](#).

DNM

See [Do-Not-Modify \(DNM\)](#).

Domain

In the ARM architecture, *domain* is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.

Memory regions domain

When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register (DACR)*. ARM deprecates any use of memory regions domains.

Do-Not-Modify (DNM)

Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Doubleword

A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

Doubleword-aligned

Means that the address is divisible by 8.

DSP

See [Digital signal processing \(DSP\)](#).

Effective value

A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an *Effective value*:

- In some cases, the description of a control *a* specifies that when control *a* is active it causes a register control field *b* to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field *b*. When control *a* is active that fixed value is described as the *Effective value* of register control field *b*. For example, when the value of HCR.DC is 1, the *Effective value* of HCR.VM is 1, regardless of its actual value.

In other cases, in some contexts a register control field *b* is not implemented or is not accessible, but behavior of the PE is as if control field *b* was implemented and accessible, and had a particular value. In this case, that value is the *Effective value* of register control field *b*.

———— **Note** —————

Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an *Effective value* in that earlier version of the architecture.

- Otherwise, the *Effective value* of a register control field is the value of that field.

Endianness

An aspect of the system memory mapping.

See also [Big-endian memory](#) and [Little-endian memory](#).

Exception

Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector

A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution stream

The stream of instructions that would have been executed by sequential execution of the program.

Explicit access

A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort

An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)

Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:

- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

FCSE

See [Fast Context Switch Extension \(FCSE\)](#).

Flat address mapping

Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode

A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers

The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

———— **Note** —————

Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
 - W0-W30 when accessed as 32-bit registers.
 - X0-X30 when accessed as 64-bit registers.

See also [High registers](#), [Low registers](#).

Generated by

The memory model is written in terms of reads from memory and writes to memory. These reads and writes:

- Are generated by instructions such as loads, stores, and atomic memory accesses.
- Correspond to the memory accesses, other than translation table walks, that are defined in the instruction pseudocode.

Some instructions generate more than one read or write.

Halfword

A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

Halfword-aligned

Means that the address is divisible by 2.

High registers

In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

———— **Note** —————

In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also [General-purpose registers](#), [Low registers](#).

High vectors

An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED

Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields

Are unsigned unless otherwise stated.

Immediate value

A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP

An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED

Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Index register	A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.
Indirect read	When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register. For more information, including additional examples of indirect reads, see Indirect read on page D12-2678 . <i>See also</i> Direct read , Direct write , Indirect write .
Indirect write	An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a Direct write to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent. For more information, see Indirect write on page D12-2678 . <i>See also</i> Direct read , Direct write , Indirect read .
Inline literals	These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.
Intermediate physical address (IPA)	An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA. <i>See also</i> Physical address (PA) , Virtual address (VA) .
Interworking	A method of working that permits branches between software using the A32 and T32 instruction sets.
IPA	<i>See</i> Intermediate physical address (IPA) .
Level	<i>See</i> Cache level .
Level of Coherence (LoC)	The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see Terms used in describing the cache maintenance instructions on page D4-2360 . <i>See also</i> Cache level , Point of coherency (PoC) .
Level of Unification, Inner Shareable (LoUIS)	The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see Terms used in describing the cache maintenance instructions on page D4-2360 . <i>See also</i> Cache level , Point of unification (PoU) .
Level of Unification, uniprocessor (LoUU)	For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see Terms used in describing the cache maintenance instructions on page D4-2360 . <i>See also</i> Cache level , Point of unification (PoU) .
Line	<i>See</i> Cache line .
Little-endian memory	Means that, for example: <ul style="list-style-type: none"> • A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address. • A byte at a halfword-aligned address is the least significant byte in the halfword at that address. <i>See also</i> Big-endian memory , Endianness .

Load/Store architecture

An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC See [Level of Coherence \(LoC\)](#).

LoUIS See [Level of Unification, Inner Shareable \(LoUIS\)](#).

LoUU See [Level of Unification, uniprocessor \(LoUU\)](#).

Lockdown See [Cache lockdown](#).

Low registers In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also [General-purpose registers](#), [High registers](#).

Memory barrier See [Memory barriers on page B2-103](#).

Memory coherency

The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory Management Unit (MMU)

Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU)

A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Miss See [Cache miss](#).

MMU See [Memory Management Unit \(MMU\)](#).

MPU See [Memory Protection Unit \(MPU\)](#).

Multi-copy atomicity

The form of atomicity described in [Requirements for multi-copy atomicity on page B2-94](#).

See also [Atomicity](#), [Single-copy atomicity](#).

NaN

Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a *quiet* NaN, that propagate through most floating-point operations, or a *signaling* NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the *IEEE Standard for Floating-point Arithmetic*.

See also [Quiet NaN](#), [Signaling NaN](#).

Natural eviction

A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Observer A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

Obsolete Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing

Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

OPTIONAL When applied to a feature of the architecture, **OPTIONAL** indicates a feature that is not required in an implementation of the ARM architecture:

- If a feature is **OPTIONAL** and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.
A feature that is **OPTIONAL** and deprecated might not be present in future versions of the architecture.
- A feature that is **OPTIONAL** but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term **OPTIONAL** are shown in **SMALL CAPITALS**.

———— **Note** —————

Do not confuse these ARM-specific uses of **OPTIONAL** with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an ARMv7-R implementation, where the **SCTLR.IE** bit indicates the implemented option.

See also [Deprecated](#).

PA See [Physical address \(PA\)](#).

PE See [Processing element \(PE\)](#).

Physical address (PA)

An address that identifies a location in the physical memory map.

See also [Intermediate physical address \(IPA\)](#), [Virtual address \(VA\)](#).

PoC See [Point of coherency \(PoC\)](#).

PoU See [Point of unification \(PoU\)](#).

Point of coherency (PoC)

For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see [Terms used in describing the cache maintenance instructions on page D4-2360](#).

Point of unification (PoU)

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see [Terms used in describing the cache maintenance instructions on page D4-2360](#).

Post-indexed addressing

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

Note

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

See also [Simple sequential execution](#).

Pre-indexed addressing

Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE)

The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

Protection region

A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit See [Memory Protection Unit \(MPU\)](#).

Pseudo-instruction

UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

PSTATE

An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also [Condition flags](#).

Quadword

A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

Quadword-aligned

Means that the address is divisible by 16.

Quiet NaN

A NaN that propagates unchanged through most floating-point operations.

See also [NaN](#), [Signaling NaN](#).

RAO

See [Read-As-One \(RAO\)](#).

RAZ

See [Read-As-Zero \(RAZ\)](#).

RAO/SBOP

In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In ARMv8, RES1 replaces this description.

See also [UNK/SBOP](#), [Read-As-One \(RAO\)](#), [RES1](#), [Should-Be-One-or-Preserved \(SBOP\)](#).

RAO/WI

Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [Read-As-One \(RAO\)](#).

RAZ/SBZP

In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In ARMv8, RES0 replaces this description.

See also [UNK/SBZP](#), [Read-As-Zero \(RAZ\)](#), [RES0](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#).

RAZ/WI

Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [Read-As-Zero \(RAZ\)](#).

Read-allocate cache

A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)

Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a [SBOP](#) policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [RAO/SBOP](#), [RAO/WI](#), [RES1](#).

Read-As-Zero (RAZ)

Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a [SBZP](#) policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [RAZ/SBZP](#), [RAZ/WI](#), [RES0](#).

Read, modify, write

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

RES0

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

———— **Note** —————

- RES0 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES0 for fields in read/write registers is:

If a bit is RES0 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
 - Reads of the bit always return 0.
 - Writes to the bit are ignored.
2. The bit can be written. In this case:
 - An indirect write to the register sets the bit to 0.
 - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES0 only in some contexts

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also [Read-As-Zero \(RAZ\)](#), [RES1](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

RES1

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

————— Note —————

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES1 for fields in read/write registers is:

If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
 - Reads of the bit always return 1.
 - Writes to the bit are ignored.
2. The bit can be written. In this case:
 - An indirect write to the register sets the bit to 1.
 - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
 - A direct write to the bit must update a storage location associated with the bit.
 - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES1 only in some contexts

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

————— Note —————

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as [SBO](#).

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an [SBOP](#) policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also [Read-As-One \(RAO\)](#), [RES0](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

Reserved	<p>Unless otherwise stated:</p> <ul style="list-style-type: none"> • Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior. • Bit positions described as reserved are: <ul style="list-style-type: none"> — In an RW or WO register, RES0. — In an RO register, UNK. <p>See also CONSTRAINED UNPREDICTABLE, RES0, RES1, UNDEFINED, UNK, UNPREDICTABLE.</p>
RISC	Reduced Instruction Set Computer.
Rounding error	The value of the rounded result of an arithmetic operation minus the exact result of the operation.
Rounding mode	Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the <i>IEEE Standard for Floating-point Arithmetic</i> , see Floating-point standards, and terminology on page A1-51.
Saturated arithmetic	Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from $+2^{31}-1$ to -2^{31} or vice versa.
SBO	See Should-Be-One (SBO) .
SBOP	See Should-Be-One-or-Preserved (SBOP) .
SBZ	See Should-Be-Zero (SBZ) .
SBZP	See Should-Be-Zero-or-Preserved (SBZP) .
Security hole	<p>A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The ARM architecture forbids security holes.</p> <p>See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.</p>
Self-modifying code	Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see Caches and memory hierarchy on page B2-111.
Set	See Cache sets .
Should-Be-One (SBO)	<p>Hardware must ignore writes to the field.</p> <p>ARM strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.</p> <p>This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.</p> <p>See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.</p>
Should-Be-One-or-Preserved (SBOP)	From the introduction of the ARMv8 architecture, the description Should-Be-One-or-Preserved (SBOP) is superseded by RES1 .
	<p>———— Note —————</p> <p>The ARMv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the RES1 definition, but not by the generic definition of SBOP given here.</p> <hr/>

Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-Zero (SBZ)

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the ARMv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by *RES0*.

———— Note —————

The ARMv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the *RES0* definition, but not by the generic definition of SBZP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Signaling NaN

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also [NaN](#), [Quiet NaN](#).

Signed immediate and offset fields

Are encoded in two's complement notation unless otherwise stated.

SIMD

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in [Parallel addition and subtraction instructions on page F1-3622](#).
- The Advanced SIMD instructions summarized in [Advanced SIMD and floating-point instructions on page E1-3542](#), when operating on vectors.

———— Note —————

In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

Simple sequential execution

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity

The form of atomicity described in *Properties of single-copy atomic accesses* on page B2-93.

See also [Atomicity](#), [Multi-copy atomicity](#).

Single-precision value

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Spatial locality

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Speculative

Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
- Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.
- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

See also [Execution stream](#).

Special-purpose register

One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- [Special-purpose registers](#) on page C5-350 specifies the AArch64 Special-purpose registers.
- [AArch32 Special-purpose registers](#) on page G1-5228 lists the AArch32 Special-purpose registers.

T32 instruction

One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also [A32 instruction](#), [A64 instruction](#), [T32 state](#).

T32 state

The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also [A32 state](#), [T32 instruction](#).

Taken locally

Taken locally is a qualifier that determines which instances of an exception are counted by particular PMU events. See, in particular, [ARM recommendations for IMPLEMENTATION DEFINED event numbers](#) on page K3-7252.

In this context, an exception that is *Taken locally* means an exception that is one of:

- Taken to the current Exception level.

Note

This is not possible when the current Exception level is EL0.

- Taken from EL0 to EL1.
- Taken from EL0 to EL2 because the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Note

An exception taken from EL0 to EL2 because the *Effective value* of HCR_EL2.{E2H, TGE} is {0, 1} is not *Taken locally*. This includes exceptions taken to EL2 using AArch32 when HCR.TGE is 1.

Temporal locality

The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction

See [T32 instruction](#).

TLB

See [Translation Lookaside Buffer \(TLB\)](#).

TLB lockdown

A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

Translation Lookaside Buffer (TLB)

A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

Translation table

A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk

The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits

In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned

An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses

Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated

Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNPREDICTABLE](#).

UNDEFINED

Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:

- Any encoding that is not allocated to any instruction.
- Any encoding that is defined as never accessible at the current Exception level.
- Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.

If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

Note

On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also [Undefined Instruction exception on page G1-5274](#).

Unified cache Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing

Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In ARMv7 and earlier versions of the ARM architecture, and in the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also [UNKNOWN](#).

UNK/SBOP Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

UNK/SBZP Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

UNKNOWN

An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

UNPREDICTABLE

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#).

VA See [Virtual address \(VA\)](#).

VFP In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

Virtual address (VA)

An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also [Intermediate physical address \(IPA\)](#), [Physical address \(PA\)](#).

Watchpoint A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way See [Cache way](#).

WI Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also [RAO/WI](#), [RAZ/WI](#), [RES0](#), [RES1](#).

Word A 32-bit data item. Words are normally word-aligned in ARM systems.

Word-aligned Means that the address is divisible by 4.

Write-allocate cache

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

Write-through cache

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

Write buffer A block of high-speed memory that optimizes stores to main memory.
