

## Classification of controllable pairs [A, B].

Let  $n \geq 1$ ,  $m \geq 1$  be fixed. Let

$\Sigma_{n,m}$  denote all possible pairs of matrices  $[A, B]$ . Clearly this is a vector space of dimension  $n^2 + nm$ .

A pair  $[A, B]$  is uncontrollable iff

$$\det \left( \sum_{k=0}^{n-1} A^k B B^T A^{T k} \right) = 0.$$

A pair  $[A, B]$  is controllable iff

$$\det \left( \sum_{k=0}^{n-1} A^k B B^T A^{T k} \right) > 0.$$

Thus  $\Sigma_{n,m}$  breaks up into two disjoint pieces  $\sum_{n,m}^{uc}$  the uncontrollable systems and  $\sum_{n,m}^c$  of the controllable systems.

The piece  $\sum_{n,m}^{uc}$  is a "thin set" since it satisfies an algebraic condition of a vanishing determinant.

This picture illustrates that what is outside

the dark, thin blob  $\sum_{n,m}^{uc}$ , makes up the controllable systems.

We are interested in showing that  $\sum_{n,m}^c$  falls into a finite number set of disjoint regions (also called equivalence classes, orbits etc) such that if  $[A, B]$  and  $[\tilde{A}, \tilde{B}]$  belong to the same region, then there is a combination of transformation of the form

$$(i) [A, B] \mapsto [PAP^{-1}, PB]$$

$P$   $n \times n$  invertible

change of basis in state space

$$(ii) [A, B] \mapsto [A + BK, B]$$

$K$   $m \times n$

state feedback

$$(iii) [A, B] \mapsto [A, BQ]$$

$Q$   $m \times m$  invertible

change of basis in input space

that take  $[A, B]$  into  $[\tilde{A}, \tilde{B}]$ .

They constitute the feedback group.

An example of such a combination is

$$[A, B] \mapsto [PAP^{-1} + PBK, PBQ].$$

Each of the transformations can be undone (relevant inverses exist). Hence,  $[A, B]$  and  $[\tilde{A}, \tilde{B}]$  are equivalent if they each can be transformed into a standard or canonical form.

For instance, when  $m=1$ , any two controllable pairs in  $\Sigma_{n,1}^c$ ,  $[A, b]$  and  $[\tilde{A}, \tilde{b}]$ , can be transformed under the feedback group into the canonical form

$$A_c = \begin{bmatrix} 0 & 1 & & & \\ & & 1 & & \\ & & & \ddots & \\ & & & & 1 \\ 0 & 0 & 0 & & 0 \end{bmatrix} \quad b_c = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 1 \end{bmatrix}$$

We saw this earlier under the setting

(4)

of single-input system eigenvalue placement theorem.

Note: We did not make use of change basis in input space for  $m=1$  since in that case it is subsumed by the special case of change of basis in state space with

$$P = qI \quad q \neq 0$$

Since,

$$[(qI)A(qI)^{-1}, (qI)b]$$

$$= [A, bq]$$

In the multi-input setting the change of basis in input space really makes a difference.

Finding invariants under feedback group

$$\text{Let } L_j = \text{im} [B \ AB \ \dots \ A^j B]$$

= linear subspace of  $\mathbb{R}^n$  spanned by columns of  $[B \ AB \ \dots \ A^j B]$ .

(5)

By hypothesis  $L_{n-1} = \mathbb{R}^n$  (controllability)

clearly

$$\text{im}(B) = L_0 \subseteq L_1 \subseteq L_2 \cdots \subseteq L_{n-1} = \mathbb{R}^n$$

Let  $\mathbb{R}^n$  be given an inner product, say Euclidean inner product.

Let  $\Lambda_j =$  orthogonal complement of  $L_{j-1}$  in  $L_j$

$$= \left\{ v \in L_j : \langle v, w \rangle = 0 \right. \\ \left. \forall w \in L_{j-1} \right\}$$

Here  $\langle v, w \rangle =$  inner product of  $v$  and  $w$ .

Then

$$L_j = L_{j-1} \oplus \Lambda_j$$

↑ direct sum of orthogonal vectors

$$\mathbb{R}^n = L_0 \oplus \Lambda_1 \oplus \Lambda_2 \oplus \Lambda_3 \cdots \oplus \Lambda_{n-1}$$

~~dim~~

Let  $r_0 = \dim L_0 = \text{rank}(B)$

$$r_j = \dim(L_j) - \dim(L_{j-1})$$

$$= \dim(\Lambda_j) \quad j=1, 2, \dots, n-1$$

Clearly  $r_0 + r_1 + r_2 + \dots + r_{n-1} = n$ .

(6)

Clearly  $r_0 > 0$  and  $r_0 \leq m$ .

Clearly  $r_j \leq m$  for  $j \leq n-1$ .

By re-ordering the columns of  $B$ , equivalently, right multiplying  $B$  by a suitable nonsingular  $Q$ , we can be sure that columns 1 through  $r_0$  of  $B$  are linearly independent. They constitute a basis for  $L_0$ .

Create the following Young diagram

	1	2				$r_0$	
$b_j$	X	X	X	X			X
$Ab_j$		X	X	X			
		X		X			
		X					
$n-1$							

with  $r_0$  columns and  $n$  rows.

Fill first row with crosses,  $r_0$  in number to mark selection of columns 1 through  $r_0$  of  $B$  as basis of  $L_0$ .

Mark a cross in second row in  $j$ th place only if  $Ab_j$  is linearly independent of all vectors  $b_1, b_2, \dots, b_{r_0}, Ab_1, \dots, Ab_{j-1}$ .  
Total # crosses in second row  
 $= r_1 = \dim(\Lambda_1) = \dim L_1 - \dim L_0$ .

In  $i$ th row mark a cross in  $j$ th place only if  $A^i b_j$  is linearly independent of all vectors  $b_1, b_2, \dots, b_{r_0}, Ab_1, \dots, Ab_{r_0}, \dots, A^i b_1, \dots, A^i b_{j-1}$ .

It follows that

$$r_0 \geq r_1 \geq r_2 \dots \geq r_{n-1}$$

We have picked basis  $S$  (by marking crosses) of vectors  $A^j b_i$  with the property that if  $A^j b_i \notin S$  then  $A^{j+l} b_i \notin S$  for  $l > 0$ .

We now associate with every  $b_i$  a number  $\kappa_i$  such that  $A^j b_i \in S$  for  $0 \leq j \leq \kappa_i - 1$  but  $A^{\kappa_i} b_i \notin S$ . Again by re-ordering the <sup>first  $r_0$</sup>  columns of  $B$ , we can achieve

$$\kappa_1 \geq \kappa_2 \geq \dots \geq \kappa_{r_0}$$

But  $\kappa_i$ 's are simply column sums of the number of crosses. Hence

$$\sum_{i=1}^{r_0} \kappa_i = \sum_{j=0}^{n-1} r_j = n$$

Sequence  $\kappa_1, \kappa_2, \dots, \kappa_{r_0}$  defines a partition of the integer  $n$ .

Remark (i)  $\kappa_i$ 's determine  $r_j$ 's and vice-versa

(ii)

After reordering in  $B$ ,

$$\{ A^j b_i : 1 \leq i \leq r_0, 0 \leq j \leq \kappa_i - 1 \}$$

← Young diagram

is a basis for  $\mathbb{R}^n$ .

(iii) under  $[A, B] \rightarrow [PAP^{-1}, PB]$

$$L_j \rightarrow PL_j \quad \text{so}$$

list  $r_0, \dots, r_{n-1}$  is invariant,  
and hence  $\kappa_1, \dots, \kappa_{r_0}$  ordered  
list of  $\kappa$ 's is also invariant.

(iv) under  $[A, B] \rightarrow [A, BQ]$

$L_j \rightarrow L_j$  so remarks  
as in (iii) apply regarding  
invariance -

(v)  $[A, B] \rightarrow [A+BK, B]$

$$(A+BK) \begin{matrix} j \\ \text{column} \end{matrix} = A \begin{matrix} j \\ \text{column} \end{matrix} + B \begin{matrix} j \\ \text{column} \end{matrix} + G$$

where  $G$  is a matrix whose  
columns are contained in  $L_{j-1}$

Hence  $L_j$  invariant under  $A \mapsto A+BK$

$\dots$   $r_j, \kappa_j$  invariant.

## Canonical Form

1. Write down pyramidal basis

$$S = \{ b_i, \dots, A^{k_i-1} b_i, \dots \mid i \in M' \} \text{ for } TR^n.$$

$M' \subseteq \{1, 2, \dots, m\}$  containing exactly  $r_0 = \text{rank}(B)$  elements

Linear dependence relations:

$$A^{k_i} b_i = - \sum_{j \in M'} \sum_{k=1}^{k_j-1} \alpha_{ijk} A^k b_j$$

$\forall i \in M'$

determine  $\downarrow$  <sup>unique</sup> coefficients  $\alpha_{ijk}$

2. New basis

$$e_{j1} = b_j$$

$$e_{j2} = A b_j + \alpha_{jj1} b_j$$

$\vdots$

$$e_{jk_{j^*}} = A^{k_{j^*}-1} b_j + \alpha_{jj1} A^{k_{j^*}-2} b_j + \dots + \alpha_{jjk_{j^*}-1} b_j$$

$j \in M'$

Direct calculation shows that in this new basis  $A$  and  $B$  take canonical forms

$$A = \begin{array}{c|c|c} \begin{array}{c} \underbrace{\begin{matrix} 0 & 1 \\ 0 & 1 \\ \vdots & \vdots \\ 0 & 0 \\ x & x \end{matrix}}_{k_1 \text{ Col}} & \begin{array}{c} \underbrace{\begin{matrix} \bigcirc & \bigcirc \\ \vdots & \vdots \\ 0 & 1 \\ \vdots & \vdots \\ 1 \end{matrix}}_{k_2} & \begin{array}{c} \bigcirc \\ \vdots \\ \bigcirc \end{array} \end{array} & \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} \\ \hline \begin{array}{c} \bigcirc \\ \vdots \\ \bigcirc \\ \vdots \\ \vdots \end{array} & \begin{array}{c} \begin{matrix} 0 & 1 \\ \vdots & \vdots \\ 1 \end{matrix} & \begin{array}{c} \bigcirc \\ \vdots \\ \bigcirc \end{array} \\ \hline \begin{array}{c} x & x & x & x & x & x & x & x & x & x \end{array} & \begin{array}{c} x & x & x & x & x & x & x & x & x & x \end{array} & \begin{array}{c} x & x & x & x & x & x & x & x & x & x \end{array} \end{array}$$

$k_1$  rows  
 $k_2$  rows

$$B = \begin{array}{c|c|c} \begin{array}{c} 0 \\ \vdots \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{array} & \begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} & \begin{array}{c} 0 \\ 0 \\ \vdots \\ 1 \end{array} & \begin{array}{c} x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \end{array} & \begin{array}{c} x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \end{array} \end{array}$$

$k_1$  rows  
 $k_2$  rows

The elements marked  $x$  in  $A$  are given by  $a_{ijk}$ . The last  $(m-r_0)$  columns of  $B$  are linearly dependent on the first  $r_0$  columns.

By applying another  $B \rightarrow BQ$  we can make last  $(m-r_0)$  columns equal to 0.

By now applying feedback  $A \mapsto A+BK$  with appropriate rows of  $K$  containing  $-a_{ijk}$  we can kill off all crosses in  $A$ . We have,

Theorem [Brunovsky]

$[A, B] \in \sum_{n,m}^c$ . Then there exist positive integers  $k_1, k_2, \dots, k_{r_0}$  uniquely determined by  $[A, B]$  such that  $[A, B]$  is equivalent under the feedback group to  $[A_0, B_0]$  where

$$A_0 = \text{diag} (E_{k_1}, E_{k_2}, \dots, E_{k_{r_0}})$$

$$B_0 = \left[ \begin{array}{cccc|c} e_{k_1} & e_{k_2+k_1} & \dots & e_{k_j+k_{j-1}+\dots+k_1} & \dots & e_n & 0 \end{array} \right]$$

$\uparrow$  column 1       $\uparrow$  2       $\uparrow$  column  $r_0$

$$E_x = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}_{k \times k}$$

Since there are finitely partitions, there are finitely many classes  $\square$
